Dr. Fishbein:—I propose to discuss the question of grants in aid and to offer my own concept of some different method of meeting the needs. I think there are needs that are required to be met. In fact, in my opening statement I said no one can disagree with the general objectives that have been stated for the Wagner act.

Senator Wagner:—That is a good beginning.

Dr. Fishbein:—Thank you, sir. I think you and I could get along very well.

Senator Wagner:—I think so, too. My son told me that.

Dr. Fishbein:—Yes, he told me he was going to tell you.

Senator Wagner:—Listening to you, I think he had tremendous courage in trying to debate the matter with you. I suppose you were generous with him.

Dr. Fishbein:—You are not going to embarrass me, I hope.

Senator Wagner:—No.

Dr. Fishbein:—When we consider the needs expressed as the result of the National Health Survey we discover that, according to the figures which are offered, approximately 17 per cent of the people with incomes of $3,000 a year or over, families with incomes of $3,000 a year or over, failed to receive or obtain medical care for chronic disabling illness. According to the same survey, 30 per cent of people with annual incomes per family of $2,000 or less failed to receive medical care for chronic disability or chronic disabling illness, and 28 per cent of people on relief failed to receive medical care for chronic disabling illness.

Senator Wagner:—You do not mind these interruptions?

Dr. Fishbein:—No, sir, I enjoy these interruptions.

Senator Wagner:—Yesterday we had a report from one of the quasi-welfare commissioners of New York.

Dr. Fishbein:—Yes.

Senator Wagner:—He said that on the present relief roll, of those receiving relief, 15 per cent were due to illness.

Dr. Fishbein:—I wouldn't doubt that. That would coincide rather well with these figures, particularly as New York in medical affairs is far beyond the rest of the country; in fact, it is stated in New York that today 50 per cent of the people receive free medical care. I am not sure of that figure, but I think your son made that statement in Brooklyn on Tuesday night. I have not yet verified it; I expect to verify it, however.

There is nothing in the National Health Survey which establishes any reason why 17 per cent of the people living in families with incomes of $3,000 a year or over fail to receive medical care. Obviously, unless all of the family's money was utilized for other purposes, something would have been available for medical care. The correction of that condition would not lie primarily in the lack of funds. I might say that I have my own concept as to why 17 per cent of people in families with incomes of $3,000 a year or over failed to receive or generally use medical care for chronic disabling illness. I am of the belief that about 10 per cent of the people of the United States do not want medical care under any circumstances. I mean even if it were put in their hands for nothing they would not take it. That is based on a survey made by the American Psychological Association, which discovered in the United States approximately twenty-seven groups who do not believe in medicine in any way, shape or form and who oppose its use whenever they can. Now obviously that would be deducted from the 17 per cent, which would leave you 7 per cent.

In the state of Massachusetts a survey was made under the supervision of the health department, using five trained medical investigators, with house to house contacts, involving 30,000 families. It indicated that only 3 per cent of the people of Massachusetts failed to receive medical care because of lack of funds, and 71 per cent of those who failed to receive medical care failed to receive it because of some breakdown in the line of communications that ought to bring those needing medical care to the places where medical care was available for them.

Obviously this question might well be argued from a philosophical point of view. It was referred to by Dr. Robb in his discussion yesterday. Obviously we do not have enough provision for the education of the public. There is a failure of the profession commonly known as social service to achieve its object of acting as a liaison between the medical profession and those needing medical service. I feel that in many instances they have been content to make a diagnosis of the condition and then not do what could be done in relationship to the correction of the condition.

Now we go to the 30 per cent of families with incomes of $2,000 a year or less who failed to receive medical care because of chronic illnesses. It is my belief that we must deduct from that figure the 17 per cent I have already mentioned in relation to those families with incomes of $3,000 a year or over. I take it the people with families with an income of $2,000 a year or under are normally intelligent but no better educated and of no finer type of intellect, which would cause them to do something that people with $3,000 a year or over would not do, leaving you a differential for that group of 13 per cent.

Again we must recognize that of the people in the United States with incomes of $2,000 a year or under we have a vast preponderance of certain poorer groups in the population, particularly the Negro group. There are perhaps from 90 to 95 per cent in the Negro group with families with incomes of $2,000 a year or under, whereas from 45 to 55 per cent of whites, roughly, would be in families with incomes of $2,000 a year or under. Thus we come to a localization of this problem, particularly in those states which the President himself has characterized as public problem No. 1. In those states the question of medical care is intimately bound with the economic situation of the state. The state of Senator Ellender is to be particularly congratulated on having made a considerable amount of progress in solving this problem by a technic developed in that state. Although I am not in a position to criticize the technic one way or the other, in any event they have answered the problem to a more considerable extent than that same problem has been answered in other states with a similar population and a similar character of medical problem.

Senator Wagner:—Isn't that also a question of providing for technical hospital service?

Dr. Fishbein:—I believe the provision for technical hospital service is a great help. I may point out that in the state of Mississippi, for example, they have 0.7 bed per thousand for the Negroes as contrasted with something like 2.3 or 2.4 for the

whites, and as contrasted with 3.5 for the population generally. The state of Mississippi certainly has not come as far as the state of Louisiana in this regard. Whether or not Mississippi can do so is a question that is to be determined.

Senator Wagner:—Doctor, right there, may I ask you if the state of Mississippi does not have the resources to take care of its quota of medical services and hospitalization that the federal government should not step in to provide those resources?

Dr. Fishbein:—I believe that no citizen of the United States for whom a demonstrated need for medical service which he is unable to supply exists should do without medical service.

Senator Wagner:—Even though it may be apparent that the federal government has to help?

Dr. Fishbein:—Yes. I believe that we are confronted here with a humanitarian problem that is outside the range of other problems.

As to the technic, again I make the reservation that I would not like to see a technic set up which would destroy democratic standards.

Senator Wagner:—Do you think we have intelligence enough to formulate methods to obtain these objects?

Dr. Fishbein:—I think we have, but sometimes we do not use it.

Moving on to the 28 per cent of persons on relief who failed to receive medical care, I point out that in many states people on relief are entitled to medical care merely by applying for it. For example, in the city of Chicago, through the state relief agency and with the aid of local funds, a system has been set up whereby any person in the community requiring medical services may apply at the relief agency and receive medical services from a physician of his choice, some 2,800 physicians having registered their names as willing to give medical service on call to any person requiring medical aid. The fees are adjusted through the relief agency by cooperative agreement between the relief agency and the medical society. The need is determined by special social service investigation under the direction of the cooperative group which has the medical care in charge. A system similar to that is the one referred to by Dr. Benson yesterday affecting the state of Oregon; again suitable relief is developed under local control, utilizing medical agencies with the assistance of state funds and without asking the federal government for a contribution. This indicates that in some places acceptable measures may be set up to solve the problem quite satisfactorily, whereas in other places the problems cannot be solved with the means or the facilities that are available.

As I have said, I am not a constitutional lawyer; I am not prepared to write an amendment; I do not believe I ought to be asked; and I do not believe the medical profession ought to be asked to amend the Wagner act. In consultation with various hospital officials as to that phase of the bill, it was pointed out that experts in the field of hospital administration would require more than 100 amendments just to fix that one portion and to coordinate it with the hospital conditions that we have in the United States today.

The Wagner bill, as I have already pointed out, would perpetuate a system of administration, through diverse agencies, which must inevitably result in duplication of effort.

As practical-minded people and with some knowledge of human psychology, we recognize the desire of an agency, once established, to continue and to expand; but of course that is not our particular concern. We recognize also the desires of various groups of people with special interests to have such agencies placed under a control where they may perhaps have a more immediate connection than under another control. For example, I notice it was the desire of two of the representatives of labor who have appeared before this committee that all functions having to do with industrial hygiene and preventive medicine in relationship to workers in industry ought not to be assigned to any of the agencies mentioned under the Wagner act. Mr. Pressman and Mr. Woll both said they would prefer to amend the act by moving those over to the Labor Department. You have that in the record of the hearings.

Senator Wagner:—I remember that very well. New York State would do it very well.

Dr. Fishbein:—That might be. I am not prepared to say. I would be willing to accept your statement, but, as I said, under this law it cannot be done successfully.

Senator Wagner:—Why?

Dr. Fishbein:—New York is a rich state. It has a vast taxing power, it has considerable funds.

Senator Wagner:—What I would like to do now under this bill—

Dr. Fishbein (interposing):— —is to equalize.

Senator Ellender:—You mentioned the rich state of New York. It gets some of its money from Louisiana and from Texas, from the natural resources throughout the country.

Dr. Fishbein:—I recognize that.

Senator Ellender:—What we want, what we desire is that the states that get the money from us give a little back to us.

Dr. Fishbein:—It is my belief that the task of attempting to equalize these matters for the forty-eight states and the territories of the United States, without a breakdown of the democratic system of government by which we have come to the point in which we now are, is not the task of the medical profession but primarily the task of the Executive and the legislators. It is the medical profession's task to maintain standards of medical service which have brought this country up to the present high place which it occupies. It is our purpose to endeavor to get the widest possible distribution of this high quality of medical service to the greatest number of people to whom it can possibly be distributed, and then if, in doing that, we can still maintain democracy, we have achieved a fine objective.

Senator Wagner:—I was interested in the cooperation because you did state earlier that you complained because you were not asked to sit down and aid in the drafting of the legislation.

Dr. Fishbein:—Yes.

Senator Wagner:—Which showed that somebody in your organization, probably your group—

Dr. Fishbein (interposing):—Not me.

Senator Wagner:—No, but it showed that somebody in your group was interested in aiding in the drafting of this legislation.

Dr. Fishbein:—I believe our function in relationship to the drafting of legislation should be to state the standards and objectives. After we have stated the standards and objectives it is up to the experts to draft appropriate legislation.

Senator Wagner:—I did not say you should be asked to sit down with those who were drafting the legislation.

Dr. Fishbein:—I think we have the function of being recognized as authorities in the field of medical practice and medical service.

Senator Wagner:—Every one wants your guidance. I misunderstood you. I thought you complained because your organization was not asked to sit in with others to draft the legislation.

Dr. Fishbein:—Senator, I made no complaint, I merely stated a fact. We were not asked.

Senator Wagner:—You said just a moment ago you should not be asked to aid in the drafting of legislation.

Dr. Fishbein:—I think that might very well be done by those who propose to draft the legislation, after such considerations as we might be able to present on the basis of our expert knowledge.

Senator Ellender:—That is all we ask you to give us now.

Dr. Fishbein:—I propose to read again now, and very carefully, and I believe with special adaptation to the circumstances that have heretofore been set up, the recommendations of our House of Delegates. In introducing it I would say we are convinced that any state in actual need for the prevention of disease, the promotion of health and the care of the sick should be able to obtain such aid without using a system that inevitably stimulates every other state to seek to develop evidence by which it can qualify for a share of the available funds. Certainly the astute minds which conceived the system of federal subsidies and grants in aid with matching appropriations should be able to develop some legislative technic which would accomplish the result without the obvious faults of this type of legislation. Our House of Delegates suggested either a federal agency to which any state in need of federal financial assistance might apply, or a new agency created specifically for this purpose, or some adaptation of the relief mechanism already in existence.

We are not constitutional lawyers, and the nation has not indicated any strong desire to change the constitution in order to make available new technics in the administration of medical service.

Let us go back to the original plan for treating here, first of all, an assemblage of all the various functions of the federal government concerning that medical care. In attempting to develop legislation of this type, in reference to certain small functions, and to keep them distributed between a variety of federal agencies, the result has been a duplication of effort and a manipulation, for various reasons and in various ways, of the funds available.

As a practical observer in affairs of this sort I have observed on occasion the systems of technic by which those desiring funds applied for them. Obviously there is nothing to prevent a man desiring funds in his state from coming to the federal officer solely in charge of making the recommendation and saying to him "What do we have to do in my state to get some of this

money?" When he is told the rules and regulations under which he must apply and under which he must develop a plan, he then develops a plan which meets the obligations and the requirements.

Furthermore, there are all sorts of technics developed for stimulating the public request for funds. If one wishes to focus on any particular problem in the health field there is well established technic for focusing attention. If the committee is interested, according to my observation, the technic is simply this: A certain amount of publicity is given to the general fact that such a question exists. The next step is to call a conference, to which various numbers of people are requested to come and contribute information, most of those requested having been determined in advance as being somewhat favorable to the idea. Then, having had all this publicity developed through the conference, more announcement of the concept is promoted in order to build up what is commonly called a demand; then the demand having been created, some one is requested to develop legislation to meet the demand.

In the present instance the medical profession has, all along this route, endeavored to insert here and there certain cautions, certain desires, certain requests, certain evidence. As I stated in the preamble to my remarks, in recognition of those desires we request a consideration of the alternative evidence.

Senator Ellender:—Doctor, you recognize that for any state to obtain any of these funds it is necessary for that state to raise its share?

Dr. Fishbein:—Under the present system of grants in aid with matching appropriations, yes, sir.

Senator Ellender:—I mean under the bill we are now considering.

Dr. Fishbein:—Yes, sir.

Senator Ellender:—Is it your view that the same technic is engaged in by the local authorities in a state?

Dr. Fishbein:—I did not gather the significance of the question.

Senator Ellender:—You say that before the demand is created it is necessary that the state itself comply?

Dr. Fishbein:—Yes, sir, and I think that such a technic may be engaged in, and sometimes quite successfully.

Senator Ellender:—And through that medium the taxpayers of that state are asked to raise their pro rata share so as to afford them the right to come up to Washington and get their share of the funds?

Dr. Fishbein:—I believe if any one presents, with a sufficient amount of urging. I have myself frequently, I am frank to say, been engaged in developing a desire for legislation in various states for the control of accidents from Fourth of July fireworks, which I believe have destroyed a great many eyes and made a great many cripples. We indicated the number of cripples that were caused each year by the Fourth of July fireworks. We published these records and released them to the newspapers and called attention to the fact that here is a serious situation. Something ought to be done about this. Pretty soon a lot of people said "Why, something ought to be done about this. People are being blinded and made cripples, and something ought to be done about this."

That is the way we have approached the Wagner Health Bill. People have said there are needs that need to be solved, there are needs that need to be met. We agree with them. We do not believe in overemphasizing the need. We have certain figures, and we have had the figures checked from various sources.

Senator Ellender:—Doctor, any plan that would be worked out you think ought to be worked out under the suggestion made by you?

Dr. Fishbein:—Made by me? By the American Medical Association.

Senator Ellender:—You are speaking for them?

Dr. Fishbein:—Yes, sir.

Senator Ellender:—Any commission, or any official charged with the authority to cover the purposes of the act, would necessarily have to listen to the citizens of all states?

Dr. Fishbein:—Yes, sir. I do not say how much he should listen.

Senator Ellender:—I am just wondering how it would be possible to hurdle the objection that you now are speaking of. In other words, in any act that is passed, Doctor, you can readily understand it is necessary to provide funds in advance.

Dr. Fishbein:—I agree with that.

Senator Ellender:—All right. Now the fund that was provided for may be sufficient to make a start.

Dr. Fishbein:—Yes, sir.

Senator Ellender:—And those funds must be distributed according to a yardstick laid in the bill. Now what is the yardstick you propose in this bill?

Dr. Fishbein:—I maintain the yardstick in this bill is so vague and indefinite in many particulars that it leaves far too much to one authority.

Senator Ellender:—Would you be able to write a yardstick?

Dr. Fishbein:—I might be able to improve the yardstick.

Senator Wagner:—Would you add or subtract?

Dr. Fishbein:—I am of the opinion that it is necessary to have a system of checks and even perhaps double checks. It can be worked out in relation to scientific research. New ideas and new developments are not accepted as such, particularly in the field where the establishment of a perfect yardstick is not yet possible. I can cite an example. I have seen a child born of an indigent family with a harelip that ought to have, at the earliest possible moment, the necessary surgery to correct that harelip. The child would otherwise be handicapped through life. It would not be able to earn what it might earn after suitable correction. I certainly would do all I could do in my own power to aid that child, to correct the harelip, if the money was not forthcoming. In most of the states excellent facilities are available to people who can get the child to the place where such facilities are available.

There is also the possibility that lop ears might interfere with the earning power of a young man. But how far out would the lop ears be before it would be recognized as a need? What agency would determine a simple thing of that sort? Could everybody desiring a correction of his appearance, in order to make a better social appearance, be entitled to bring that in as a need to a medical agency?

I can give you other diseases much more significant. Let us say we have the question of the syphilitic. We have a bill providing three million the first year and five million the second, and then up as far as Congress cares to appropriate to handle that particular problem. Now then there are in the United States a certain number of the syphilitic who are a menace to every one who is anywhere around them. There are a considerable number of cases of latent syphilis whose Wassermann reaction is positive but who would not be a menace to everybody around them. They have a positive test. Sometimes you can treat the patient for years without getting a negative Wassermann reaction yet they can go on with their work without bothering anybody. The doctor can enjoy himself treating them for a long period of time, sometimes with considerable success and sometimes with no success. Who is to set up a yardstick? Shall we set up the yardstick that every man is conceded to be entitled to free treatment for his syphilis until he gets a negative Wassermann reaction? If you do, then the money you have appropriated will not begin to meet the problem. The doctors do not feel the negative Wassermann reaction or the positive Wassermann reaction should determine whether a man becomes a charge on the community.

Senator Wagner:—Doctor, there have been diverse criticisms of those standards set up. Some say they are too restrictive. You make the criticism that they are too vague. Have you in mind now some standards that might be provided?

Dr. Fishbein:—I do not believe I could have in mind such a standard. I do not believe any individual you can get up here, including the best authorities in the United States, could stand here and elaborate the vast system of standards that would be necessary. I need only refer to the attempt to set up suitable standards in relationship to medical care of veterans or in relationship to any sort of medical care at public expense. Committees have sat for days, weeks and months endeavoring to study these expenditures in relation to the care of patients and even yet these standards are constantly subject to change.

Senator Wagner:—When you made the criticism I thought you had in mind some definite way in which it could be corrected.

Dr. Fishbein:—I do not think it could be. I believe the only system would be relative to suitable judgment, based on properly integrating each problem in the general scheme. A problem would then be entitled to have funds devoted to it in any individual state without forcing the development of such a need in some other state. I do not believe the need of New York in relation to some of these conditions is as great as the need in some other states.

Senator Wagner:—That is undoubtedly true. I was trying to think nationally.

Dr. Fishbein:—That is the way I am thinking all the time. Having the picture before us, obviously there must be some system of check and, as I have said, double check. After you have given the money you should be absolutely sure that the

money has been well spent. There must be investigations. The Public Health Service could go out and resurvey occasionally.

Senator Murray:—The government follows that system of checks in connection with the PWA. They have engineers on each project.

Dr. Fishbein:—I think there should be something similar in relation to devotion of funds for medical purposes.

Senator Wagner:—I think there is.

Dr. Fishbein:—I doubt that there is; or, if there is, it is not functioning 100 per cent.

Senator Wagner:—Is not the maternal care, child care and the health service, is not that done very well, very efficiently by the federal government today in granting aid to states?

Dr. Fishbein:—Senator, I can send you copies of various reports that have been made by independent investigating agencies, but I do not care myself to be put into the position of standing here criticizing the conduct of any special governmental department in this field.

Senator Wagner:—I was not going to ask you to criticize any governmental department, except I always understood that was particularly efficiently run.

Dr. Fishbein:—I will be glad to send you a report made by an independent and unbiased investigating agency as to the manner in which the funds were used under the Sheppard-Towner bills, as to where the money was spent, what was done with it and what was accomplished.

Senator Wagner:—The reason I am particularly interested is that some of the other witnesses testifying, Doctor, have contended the provisions were too restrictive, that the federal government was attempting to control the activities of the states by simply seeing that the moneys were expended for the purposes for which they were employed. Now you take the other point of view, and I am sympathetic with your point of view, that there ought to be supervision of the moneys that are spent by the states.

Dr. Fishbein:—Supervision and checking.

Senator Wagner:—There have been some of your fellow doctors who have taken the contrary view.

Dr. Fishbein:—That is between you and them.

Senator Murray:—These reports you referred to, Doctor, will be sent to the committee?

Dr. Fishbein:—I will arrange to have the reports sent, yes, sir. I hope my associates are taking note of it. We already have begun the report on each federal department concerning medical care and the amount of money spent.

Senator Murray:—Doctor, in view of your knowledge and evident efficiency in this field, I would like to see you take this bill of ours and sit down and analyze it section by section for us.

Dr. Fishbein:—I will ask my associates to aid in such analysis of the bill. We have gentlemen who are well versed in the public health portions of it, who could make a complete analysis of the bill, but I would indicate the extreme difficulty, if not almost an impossibility of doing much with this bill as it now stands.

Senator Murray:—It is not necessary to do anything with the bill.

Dr. Fishbein:—Well, Senator, our analysis goes to our corrections.

Senator Murray:—Would you have difficulty in analyzing each section?

Dr. Fishbein:—I am sure that Dr. Woodward of the Bureau of Legal Medicine and Legislation and Dr. Leland of the Bureau of Medical Economics, and Dr. West, will all participate in that report.

Senator Ellender:—Doctor, in making your analysis and criticism I want you to offer suggestions.

Dr. Fishbein:—I have made some, and if I think of any others I will be delighted to make them.

Senator Ellender:—I mean with reference to each section of the bill, beginning with title I.

Dr. Fishbein:—I think the chief difficulty of the bill is the endeavor to make it all inclusive, with obviously inadequate multiple agencies. Thank you.

Senator Murray:—Thank you, Doctor, for your comprehensive statement.

Dr. Cary:—Mr. Chairman, I wish to thank you on behalf of the American Medical Association for the courteous treatment you have accorded the American Medical Association.

ABSTRACT OF STATEMENT BY MISS MILDRED SCHPEISER

Subsequent to the appearance of the representatives of the American Medical Association, hearing was given to Miss Mildred Schpeiser, who appeared on behalf of the American Youth Congress and who seemed to be largely concerned with sex education. She supported the National Health Program, stating "As organized youth, 8,000,000 strong, we are already especially concerned with this matter of adequate medical care. . . . We see this bill as the first step toward the goal."

ABSTRACT OF STATEMENT BY DR. C. C. LUND

Next appeared Dr. Charles C. Lund, representing the Massachusetts Medical Society. He opposed the Wagner bill, stating that his Committee on State and National Legislation of the Massachusetts Medical Society was unanimous in opposition to the Wagner Health Bill in its present form. Dr. Lund supported in general the objectives stated by the representatives of the American Medical Association.

ABSTRACT OF STATEMENT BY DR. J. A. O'HARA

Next appeared Dr. J. A. O'Hara, president of the Louisiana State Department of Health, who stated that they would favor legislation, subject however to a number of suggestions for modifications, including support for general hospitals already existing, asking the state medical advisory council to be appointed by the state medical societies, asking that all health and medical service be placed under the exclusive jurisdiction of the United States Public Health Service. He indicated that in Louisiana there are 100,000 people medically indigent, 6,000 cases of tuberculosis without suitable care, approximately 10,000 children requiring orthopedic care and hospitalization, and he feels that an increase in the amount of money appropriated for beds in mental hospitals is warranted.

ABSTRACT OF STATEMENT BY DR. A. T. MCCORMACK

Next appeared Dr. A. T. McCormack, Louisville, state health commissioner of Kentucky. Dr. McCormack presented a resolution adopted by the Conference of State and Provincial Health Authorities of North America. Eliminating the provincial representatives, they urged the passage of sections 1, 2, 3 and 5 of the National Health Program, opposed the compulsory health insurance, and asked for unification of all federal public health agencies in a national department of health. He stated that usually plans developed in the states are accepted without change or amendment by federal authority. He discussed at length the mechanism of public health administration in Kentucky. Dr. McCormack said "I think the report of the Technical Committee is one of the greatest documents that has ever been written on social welfare in the history of mankind." Dr. McCormack stated that surveys had been made in many of the counties of Kentucky in cooperation with the American Medical Association's survey and that as a result a resolution had been adopted urging the creation of a Bureau of Medical Service in the Division of Local Health Work of the State Department of Health whose duties it shall be to assist the legally qualified and registered medical profession of Kentucky in providing complete service for the indigent and the medically indigent residents of the commonwealth. Dr. McCormack suggested amendments to the Wagner Health Bill calling for unification of the different agencies and calling for utilization of existing hospital facilities. He said there was no reason why it would be difficult to amend the Wagner Health Bill, and he suggested a preamble to the effect that it is the express purpose of the act that no plan approved under it shall provide for the regimentation, federalization or socialization of the practice of medicine, and that it is its express intent to provide for the continuation of the private practice of medicine, which has brought to the people of the several states the benefits of scientific research and medical care. Dr. McCormack stated that the matter of training personnel had been so completely misconstrued that it is astonishing, and that he could not understand the attitude of the previous representative on subsidies for medical education.

ABSTRACT OF STATEMENT BY DR. FELIX J. UNDERWOOD

Next was Dr. Felix J. Underwood, Jackson, Miss., secretary of the state board of health. Dr. Underwood stated that he did not feel the proposed act would "establish a system of health insurance or require the states to do so." He confined his remarks to titles V and VI and stated that he found some objections in some of the other titles. He agreed with Dr. McCormack on the necessity for utilization of existing beds. He said "If every state and local governmental agency could have had the experience extending over many years that has been enjoyed by the state health authorities in dealing with the Children's Bureau and the Public Health Service, 'the wolf cry of bureaucracy and federal domination and control' would never have been raised."

ABSTRACT OF STATEMENT BY MR. DOUGLAS V. SVENSON

Douglas V. Svenson, Deputy Commissioner of Public Welfare for Louisiana, said that the people of the state of Louisiana wholeheartedly favored the principles of the proposed National

Health Act. He thought the bill ought to be revised to give opportunity for use of state-owned and operated facilities that have been constructed since Jan. 1, 1936. He stated that he was wholeheartedly for the bill.

ABSTRACT OF STATEMENT BY DR. C. E. LARIO

Next Dr. Clarence E. Lario, Baton Rouge, president of the Louisiana State Medical Society, stated that he thought the medical profession representatives appeared "with a red flag flaring in front of them, definitely opposed to all form of reform . . . but gradually they became a little more cooperative." He stated that he trusted the committee would, in all sincerity, work with the American Medical Association and the various state societies.

Session of June 1

Before the subcommittee of the Committee on Education and Labor on June 1 Senator Shipstead appeared, stating that he was himself a dentist for twenty years before coming to the Senate, and asked consideration of representatives of the dental profession whom he then presented.

Dr. C. Willard Camalier, past president of the American Dental Association, stated that there are 62,000 practicing dentists in the United States and that 47,000 are members of the American Dental Association. He introduced Dr. Harold Oppice, chairman of the National Health Program Committee of the American Dental Association, who presented the considerations of the American Dental Association relative to the National Health Program and also special considerations of the difficulties with S. 1620. He believes that dentistry should have a separate title in the bill and made proposals by which dentistry can participate in the National Health Program. He pointed out that dentistry and dental services are not mentioned in any line or title of the bill. It was his belief that the bill might lead to a system of compulsory health insurance.

ABSTRACT OF STATEMENT BY DRS. MORREY AND WALLS

Dr. Morrey, Director of Public Relations, estimated that it would take $60,000,000 a year to take care of the dental aspects of service to indigent children, including an educational program plus operative care. It was impossible to estimate the cost for adults. Senator Murray stated to Dr. Walls that the Senate subcommittee would like to have from the dental profession the amendments or proposals necessary to cover dentistry in the health bill. Dr. Walls suggested that it would require until the first of August to develop these and asked if that would be too late. Senator Murray said "I do not think so. It is not going to be possible for us to have this bill enacted in this session, so that would be perfectly proper. Dr. Wall also stated that these hearings were the first time official Washington considered that dentistry played a big part in the health of the nation.

ABSTRACT OF STATEMENT BY DR. P. G. SMITH

Dr. Park G. Smith, president of the Ohio State Medical Association, explained its opposition to the National Health Bill, emphasizing many of the points emphasized by representatives of the American Medical Association. Senator Murray said "I am very much in accord with your views with reference to the bearing of the economic conditions on this subject of national health. I think your observations there are very wise, and I think that improvements in that field will go a long way toward remedying the health situation too."

ABSTRACT OF STATEMENT BY MR. J. G. CROWNHART

Mr. J. G. Crownhart, secretary of the State Medical Society of Wisconsin, discussed particularly that section of the bill on grants to states for medical care. He submitted to the committee his report on health insurance abroad. He said "The Wagner bill is so designed as virtually to insure the inauguration of state compulsory sickness insurance plans subject to the control and direction of the federal government."

ABSTRACT OF STATEMENT BY MR. JAMES E. SLOCUM

In the afternoon session first appeared James E. Slocum, research director for the National Chiropractic Association, who recommended that the committee always keep in mind the right of the citizen to choose his own doctor and method of healing and urged that the committee include doctors of chiropractic in the federal health program. In the discussion with the committee, he said that there were approximately thirty chiropractic colleges in the country, many of them standardized on the four year course, and that they graduate between 2,000 and 2,500 a year, and that there are between 15,000 and 16,000 practitioners. He said the difference between his profession and osteopathy was philosophical. He did not think that of recent years the medical profession opposed the theory of chiropractic so much. He said that chiropractors are now licensed in forty-three states and that there are approximately 40,000 drugless practitioners in America.

ABSTRACT OF STATEMENT BY MR. ABRAHAM EPSTEIN

Abraham Epstein of the American Association for Social Security said that he was no enthusiast of the bill, that from 40 to 50 per cent of people in the low income group do not get medical care. They want a self-respecting independent system whereby they can distribute their costs. He said that insurance is the proper method for doing this and that insurance fits most aptly in sickness. He suggested, therefore, compulsory health insurance. He objected to the bill because it tries to compromise with the American Medical Association and practically gives them everything, and yet they try in their general stupidity to come out and say that the one thing that they object to is the health insurance program. He also said that in a health insurance program you can have the least governmental interference. All that the government does is to collect. He endorsed everything in the bill except the administrative feature in the last provision. He did not think that they would accomplish anything, however, by passing the whole bill. He said he did not know what was in the bill even the day before it was introduced, and that he thought this was an attempt to compromise with the American Medical Association. Further he said "If they had asked me, and I am an old bird at that thing, I would have said right at the start that there is no chance for you ever to get Dr. Fishbein and his crowd to accept anything, no matter what statements they issue." He said the defect of the bill was the fact that it tried to avoid health insurance. He said "Senator Wagner has made several statements. Before the doctors he states that there is no health insurance here. I can tell you, you really could have a health insurance program under this bill. I don't think that these tactics will do any good. That is no way of fooling the American Medical Association; it cannot be done, and I do not think that there is any possible chance of converting them." Senator Wagner said that there was nothing in the bill to compel a health insurance program by any state. Mr. Epstein said that this was his objection to the bill. He then urged the passage of the Capper bill, which is a health bill now before the Committee on Finance.

ABSTRACT OF STATEMENT BY MR. W. F. MONTAVON

Next appeared Mr. William F. Montavon, director of the legal department of the National Catholic Welfare Conference. He found that the Wagner bill fails to provide for and indeed would make impossible in some cases any cooperation of governmental and nongovernmental agencies, that it would divide the elements now providing medical care into two rival groups, those serving under a state plan and those not so serving. Between these two groups there would be no place for the nongovernmental agency. He feels that it should be compulsory on the government to give preference to the private hospital, which is an American tradition. He said that the conference of the hospital agencies with the Interdepartmental Committee had not influenced in any way its report. He also left with the committee an analysis of the Social Security Law and S. 1620.

ABSTRACT OF STATEMENT BY MONSIGNOR JOHN O'GRADY

Next appeared Monsignor John O'Grady, secretary of the National Conference of Catholic Charities, who discussed particularly the interest of the private charity and the private hospital.

ABSTRACT OF STATEMENT BY REV. A. M. SCHWITALLA

Rev. A. M. Schwitalla, representing the Catholic Hospital Association, discussed the costs of hospitals and described the work of the Catholic Hospital Association, and the actions of the Joint Committee of the three national hospital associations. He said that "the National Health Act not only ignores the partnership which has existed traditionally between the public and private agencies but it places the public agencies into a position in which we believe they will sooner or later constitute an actual menace to the non-tax supported hospital." He said that "the act recommends a pattern of governmental dominance over health care tried in its implications only in those countries in which the American form of democracy is unknown. He felt that there was no way to amend S. 1620 satisfactorily but that there should be drafted a new bill. He filed with the committee a report of the three hospital associations relative to the bill.

ABSTRACT OF STATEMENT BY MR. BRYCE L. TWITTY

Mr. Bryce L. Twitty, president of the American Protestant Hospital Association, supported the same general point of view as did also Dr. Claude W. Munger, representing the American Hospital Association. He stated that the bill was not satisfactory in its present form, that it must be given more study and that there must be important amendments.

(To be continued)

OFFICIAL NOTES

RADIO BROADCASTS

The radio broadcasts by the American Medical Association and the National Broadcasting Company, under the title Your Health, continue as previously announced each Wednesday over the Blue network of the National Broadcasting Company at 1 p. m. eastern standard time (12 noon central standard time, 11 o'clock mountain time, 10 a. m. Pacific time).

Starting April 30, daylight saving time took effect in Chicago. The program is therefore being broadcast at the same hour Chicago daylight saving time, which means one hour earlier central standard time, two hours earlier mountain time and three hours earlier Pacific time. In communities where daylight saving time is in effect there is no change in the hour of the broadcast.

Owing to network conflicts the Chicago broadcast does not occur at 1 o'clock Wednesday but there is a rebroadcast from a recording over station WENR at 8 o'clock each Wednesday evening (8 o'clock Chicago daylight saving time, 7 o'clock central standard time). The program broadcast each Wednesday evening is identical with the network program of Wednesday afternoon.

The last program to be broadcast, together with its date and topic is as follows:

June 21. Better Babies.

This terminates the fourth series of dramatized programs, and the sixth consecutive season of broadcasting over the networks of the National Broadcasting Company. Announcements as to further radio programs will appear in THE JOURNAL in advance of the dates scheduled.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. 2353 and H. R. 6225 have been reported to the Senate and House respectively, proposing to authorize an appropriation to construct a medical school building at Carlisle Barracks, Pennsylvania. H. R. 6635 has passed the House, proposing to amend in several respects the Social Security Act. This bill proposes, among other things, (1) to freeze the old-age insurance tax at 1 per cent on the employee and on the employer for the three years 1940, 1941 and 1942; (2) that only the first $3,000 an employer pays an employee for a year is to be taxable under the unemployment compensation provisions; (3) to liberalize certain benefits; (4) to exclude from the provisions of the act service performed as a student nurse in the employ of a hospital or a nurses' training school by an individual who is enrolled and is regularly attending classes in a nurses' training school chartered or approved pursuant to state law and service performed as an intern in the employ of a hospital by an individual who has completed a four year course in a medical school chartered or approved pursuant to state law.

Bills Introduced.—S. 2543, introduced by Senator Neely, West Virginia, proposes to accord all the benefits now given to veterans of the World War to persons who served as members of boards to carry out the provisions of the selective draft act. S. 2547, introduced by Senator Murray, Montana, proposes to impose additional duties on the United States Public Health Service in connection with the investigation, treatment and control of tuberculosis. The bill provides federal subsidies to assist states, counties, cities, health districts and other political subdivisions of the states to establish, extend and improve measures for the prevention, treatment and control of tuberculosis, including the provision of facilities for sanatoriums and other care for persons with tuberculosis. The U. S. Public Health Service will be authorized to make studies, investigations and demonstrations to develop more effective measures of prevention, treatment and control of the disease. For the fiscal year ending June 30, 1940, the bill proposes to authorize not exceeding the sum of $7,750,000, for the fiscal year ending June 30, 1941, not exceeding the sum of $33,500,000, for the fiscal year ending June 30, 1942, not exceeding $37,000,000, and for each fiscal year thereafter, such sum as may be necessary, provided that subsequent to the fiscal year 1945 the federal appropriations authorized shall not exceed $17,500,000. H. J. Res. 316, introduced by Representative May, Kentucky, proposes (1) to establish a federal department of public health as an independent agency under the executive branch of the government to which will be transferred all public health activities and services financed wholly or in part by the federal government, with the exception of the Army, Navy and Veterans' Administration services; (2) that it shall be unlawful for any person to use any seal, stamp or certificate of another person denoting or implying superiority in purity, quality, usefulness or effectiveness of any drug, food, cosmetic, therapeutic lotion, therapeutic device or diagnostic and surgical assists, unless authorized by the rules and regulations of the United States Public Health Service; (3) to provide that disability on account of sickness shall be considered, under the Social Security Act, as unemployment after three days of such disability and until the termination of such disability; (4) that there shall be established in the District of Columbia a United States Medical and Surgical College to which graduates of accredited medical and surgical colleges shall be admitted for training for Army, Navy or public health work, on designation by senators and representatives in Congress. The college will be authorized, it is proposed, to provide medical, surgical and clinical facilities for the diagnosis and treatment of all types of illness and physical and mental disabilities, the facilities to be available for all patients whose income is not in excess of $600 per annum, if single, or $1,200 per annum if married and supporting dependents; (5) to create a joint congressional committee to make a thorough study of all public health problems and to recommend to Congress a system whereby individuals in the low-income groups may be able to purchase full coverage insurance to cover the costs of sickness "in lieu of federal and state grants-in-aid."

DISTRICT OF COLUMBIA

Changes in Status.—S. 1805 has been reported to the Senate, without amendment, proposing to establish a lien for moneys due hospitals for services rendered in cases caused by negligence or fault of others. H. R. 6509 has been reported to the House, proposing to provide for insanity proceedings in the District of Columbia.

FRENCH SICKNESS INSURANCE

The French system of sickness insurance is following the example of nearly all other systems by showing a constant and fairly rapid increase in expenditures. According to the *Monthly Labor Review* (48:312 [April] 1939) the increases in payments since 1930 are as follows:

Disbursements by Sickness Insurance in France, 1930 to 1936

Year	Disbursements (in Francs)
1930-1931	714,644,616
1932	875,873,375
1933	935,401,696
1934	998,126,448
1935*	1,097,925,128
1936*	1,011,279,135

* Provisional figures.

This increase is somewhat exaggerated by the depreciation in the franc, which is now quoted at 2.65 cents. Since January 1937 the contribution for all types of social insurance has amounted to 8 per cent of the wage, with a maximum of 100 francs a month.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

State Medical Election.—Dr. Delamere F. Harbridge, Phoenix, was chosen president-elect of the Arizona State Medical Association at its recent annual session in Phoenix, and Dr. Charles S. Smith, Nogales, was installed as president. Other officers include Drs. Dan L. Mahoney, Tucson, vice president; Leslie R. Kober, Phoenix, secretary, and Clarence E. Yount, Prescott, treasurer. Dr. Harbridge was secretary of the association from 1917 until this year; in 1937 he was presented with a solid gold diamond studded badge emblem in appreciation of his having served twenty years in the position. He is also an honorary member of the Philadelphia County Medical Society.

ARKANSAS

State Medical Meeting and Election.—Dr. Henry T. Smith, McGehee, was chosen president-elect of the Arkansas Medical Society at its annual session in Hot Springs National Park May 8-10 and Dr. Albert S. Buchanan, Prescott, was installed as president. Other officers are Drs. John M. Proctor, Hot Springs National Park, Berry L. Moore, El Dorado, and Thomas J. Stewart, Wynne, vice presidents; Royal J. Calcote, Little Rock, treasurer, and William R. Brooksher, Fort Smith, secretary. The 1940 convention will be held in Fort Smith. The scientific program included the following out of state speakers:

Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, American Medicine and the National Health Program.
Dr. Arthur E. Hertzler, Halstead, Kan., Cardiotoxic Goiter.
Dr. Joseph Brennemann, Chicago, Appendicitis in Children.
Dr. Tinsley R. Harrison, Nashville, Value of Drugs in Treatment of Cardiac Disease.
Dr. Elmer D. Twyman, Kansas City, Mo., Some Experiences in the Treatment of Cancer.
Dr. William R. Cubbins, Chicago, *Fractures of the Neck of the Femur.*
Dr. Jefferson C. Pennington, Nashville, Tenn., Painful Nephroptosis and Its Treatment.
Dr. Louis T. Byars Jr., St. Louis, Repair of Open Wounds and Deformities Resulting from Burns.
Dr. Louis Rudolph, Chicago, The Management of the Prolonged First Stage of Labor.

A public meeting Monday was addressed, among others, by Dr. Hertzler on "The New Deal in Medicine" and Dr. Fishbein, "Fads and Quackery in Healing."

CALIFORNIA

Eleven Encephalitis Cases Following Measles.—In an epidemic of measles in San Francisco from September 1938 until about the first of May, there were eleven cases of postmeasles encephalitis. Six deaths occurred in a total of 10,236 cases of measles, five of which were recorded in the group presenting encephalitis. According to the *Bulletin of the San Francisco County Medical Society*, the first case of postmeasles encephalitis in the last twenty years was reported in 1936. In the 1938-1939 epidemic three cases were reported from private hospitals and eight cases from the San Francisco Hospital. The onset of the encephalitis was nearly always sudden, developing a few days after the onset of the measles rash. Convulsions were present in eight cases and a significant part of all the fatal cases; paralysis of the lower extremities was recorded in three cases.

DISTRICT OF COLUMBIA

Personal.—Dr. J. Winthrop Peabody has written that he has not resigned as general superintendent of the District tuberculosis hospitals to devote his entire time to private practice as reported in THE JOURNAL, May 27, page 2181. The item was based on a newspaper report.

FLORIDA

State Medical Meeting and Election.—Dr. John S. Turberville, Century, was chosen president-elect of the Florida Medical Association at its annual meeting in Daytona Beach May 1-3, and Dr. Leigh F. Robinson, Fort Lauderdale, was installed as president. Other officers include: Drs. James Ralston Wells, Daytona Beach, Thomas H. Bates, Lake City, and Joseph W. Taylor, Tampa, vice presidents, and Shaler A. Richardson, Jacksonville, secretary-treasurer. The 1940 session will be held in Tampa. The speakers on the scientific program included:

Dr. William C. Roberts, Panama City, Puerperal Infections versus the General Practitioner.
Dr. Ferdinand Richards, Jacksonville, Five Hundred Consecutive Operative Gynecological Cases.
Dr. Erasmus B. Hardee, Vero Beach, Treatment of Automobile Accidents.
Dr. James Frank Wilson, Jacksonville, Some Observations on the Treatment of Pellagra.
Dr. Alva T. Cobb Jr., Gainesville, Eugenic Sterilization.
Dr. Wilbur A. McPhaul, Jacksonville, Public Health Yesterday, Today and Tomorrow.
Dr. Nathaniel L. Spengler, Tampa, The Thyroid and Adrenal Glands: Factors in the Control of Fever, Heat Regulation and Climate.
Dr. John Webster Merritt, Jacksonville, Hyperthyroidism—Medical Phases.
Dr. William Duncan Owens, Miami, Hyperthyroidism—Surgical Aspects.
Dr. Sherman B. Forbes, Tampa, Atrophic Rhinitis and Otosclerosis.
Dr. Robert L. Elliston, Fort Lauderdale, Importance of Case Records Relative to the Cancer Problem.
Dr. William W. McKibben, Miami, Pediatrics Fifty Years Ago and Today.
Dr. Robert B. McIver, Jacksonville, Management of Injuries to the Ureter.
Drs. Arthur H. Weiland and Charles R. Burbacher, Coral Gables, Treatment of Hip Fractures by Internal Fixation.
Dr. Hugh West, DeLand, Acute Intestinal Obstruction: Diagnosis and Physiologic Treatment.
Dr. Lloyd J. Netto, West Palm Beach, Acute Appendicitis.
Dr. Ralph A. Gowdy, Miami Beach.

Other societies meeting at this time were the Florida Radiological Society, Florida Pediatric Society, Florida Railway Surgeons Association, Florida Internists Society and the Florida Society of Dermatology and Syphilology.

GEORGIA

Society News.—Among others, Dr. Madison Hines Roberts discussed intracranial hemorrhage in the newborn before the Fulton County Medical Society, Atlanta, May 4, and Dr. John Calvin Weaver, "A Simple Appliance for Continual Drainage of the Spinal Canal in Meningitis." Dr. William R. Crowe Jr., Atlanta, addressed the society May 18 on "Low Nodal Paroxysmal Tachycardia with Report of Case Treated with Monopotassium Phosphate" and Dr. Wadley R. Glenn, Atlanta, "Appendicitis: Factors Influencing Its Mortality and Morbidity in the Negro."

Changes in Health Officers.—Dr. Charles C. Hedges, senior medical officer, Federal Trade Commission, Washington, D. C., has been appointed health officer of Savannah and Chatham County. Dr. Glenn J. Bridges, Millen, health officer for Jenkins County for two years, has been appointed assistant city and county health officer; this position has been vacant since the death of Dr. Alfred Larson last year, who died the same day as did the health officer Dr. Victor H. Bassett. Dr. Thomas H. D. Griffitts, U. S. Public Health Service, has been acting health officer. Dr. Robert F. Young, Cartersville, has resigned as health officer of Bartow County to enter private practice in Hope, Ark., it is reported.

IDAHO

Annual Registration Due July 1.—All practitioners of medicine and surgery holding licenses to practice in Idaho are required by law to register annually on July 1 with the Department of Law Enforcement and at that time to pay a fee of $2. If a licentiate has not paid the annual registration fee by October 1 his license can be canceled but will be restored within five years thereafter on payment of the delinquent fees and a $10 penalty. If a license has been canceled for more than five years, it can be reinstated only on the payment of $25 and on the licentiate's passing an examination, the nature of which shall be determined by the Department of Law Enforcement.

ILLINOIS

Society News.—Dr. George B. Eusterman, Rochester, Minn., addressed the Rock Island County Medical Society in Rock Island May 9 on "Recent Important Advances in the Diagnosis and Treatment of Gastroduodenal Disease."——Dr. Michael H. Streicher, Chicago, addressed the St. Clair County Medical Society in Belleville June 1 on "Diseases of Colon and Rectum and Proctoscopic Examination."——At a meeting of the Bureau County Medical Society, Princeton, May 9, Dr. James H. Mitchell, Chicago, discussed "Diagnosis and Treatment of Common Dermatoses."

Chicago

Annual Meeting of Chicago Medical Society.—Dr. Rock Sleyster, Wauwatosa, Wis., President of the American Medical Association, will be the guest of honor at the annual dinner meeting of the Chicago Medical Society at the Palmer House June 21. Dr. Charles B. Reed will be toastmaster. Entertainment and a dance have been arranged.

Course on Glaucoma.—An intensive course on glaucoma will be presented at the Illinois Eye and Ear Infirmary for five days beginning September 11 under the direction of Dr. Harry S. Gradle. The course will be limited to ten physicians who are practicing ophthalmology alone or with otolaryngology. About forty members of the staff will give the instruction, which will consist of two hours of lectures each day with demonstrations and practical instruction the remainder of the day. The plan also includes luncheons with round table discussions. The details may be obtained from Dr. Samuel J. Meyer, secretary of the course, Illinois Eye and Ear Infirmary, 908 West Adams Street.

INDIANA

Committee to Conserve Vision.—The Indiana State Medical Association has appointed a committee on the conservation of vision. The resolution authorizing the creation of the committee outlines its duties as follows: (1) to encourage ocular hygiene, (2) to disseminate knowledge for the prevention of blindness and the conservation of vision, (3) to acquaint the public and particularly industries and schools concerning proper illumination and other protective measures for the eyes, and (4) to help create and advise sight conservation classes.

State Tuberculosis Meeting.—The twenty-eighth annual session of the Indiana Tuberculosis Association was held at the Hotel Lincoln, Indianapolis, April 18-19. The speakers were, among others, Drs. Henry C. Sweany, Chicago, on "The Tuberculosis Problem Viewed in the Light of Recent Pathologic Studies"; Paul A. Teschner, Chicago, "Telling the Public the Facts," and Mr. Holland Hudson, New York, "Current Commonplaces of Rehabilitation." Woodson S. Carlisle, South Bend attorney, was chosen president, succeeding Dr. Maurice R. Lohman, Fort Wayne.

KENTUCKY

Society News.—Drs. Charles Harold Avent and W. Likely Simpson, Memphis, Tenn., addressed the Fulton County Medical Society, Hickman, recently on "Ruptured Appendix" and "Foreign Bodies in the Trachea, Esophagus and Bronchi" respectively.——At a recent meeting of the Calloway County Medical Society, Murray, the speakers were Drs. Edison D. Fisher and Coleman J. McDevitt on Buerger's disease and diabetes, respectively.——Dr. Louis Wallace Frank, Louisville, addressed a public meeting sponsored by the Grant County Medical Society in Williamstown in April on cancer.——Dr. Delmas K. Kitchen, Detroit, addressed the Boyle County Medical Society, Danville, April 19 on "Clinical Endocrinology."——Dr. E. Murphy Howard, Harlan, addressed the Letcher County Medical Society, Whitesburg, April 25 on "Gonorrhea and Its Complications."——At a recent meeting of the Licking Valley Medical Society in Dry Ridge the speakers were Drs. William E. Gardner on dementia praecox; William J. Martin Jr., rectal diseases, and William Austin Bloch, influenza. All are of Louisville.

MAINE

State Medical Meeting.—The eighty-seventh annual session of the Maine Medical Association will be at Poland Spring House, Poland Spring, June 25-27, under the presidency of Dr. Willard H. Bunker, Calais. Out of state speakers will include:

Dr. Merrill J. King, Boston, External Diseases of the Eye.
Dr. Paul A. Chandler, Boston, Glaucoma.
Dr. Francis C. McDonald, Boston, Some Pediatric Problems of the Respiratory Tract.
Dr. James S. Greene, New York, Speech Defects.
Dr. Francis G. Blake, New Haven, Conn., The Chemotherapy of Pneumonia.
Dr. John J. Moorhead, New York, Treatment of Ordinary Injuries.
Dr. John T. Morrison, New York, Rural Community Hospitals.
Dr. Gordon M. Morrison, Boston (subject not announced).

Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will speak at the banquet Tuesday evening on "American Medicine and the National Health Program." Fifty-year service medals will be presented at the banquet to Drs. Charles B. Sylvester, Portland; Gustav A. Pudor, Portland; Bernard A. Bailey, Wiscasset (posthumously), and Henry I. Durgin, South Eliot. The past presidents' and county secretaries' luncheon will be held the same day. The scientific program also includes a round table discussion on postoperative complications, a symposium on psychoanalysis and one on traumatic surgery, and a clinicopathologic conference with summations on each case by Dr. Reginald Fitz, Boston. There will be a conference of the Medico-Legal Society Tuesday morning.

MARYLAND

New Officer in Charge of Quarantine Station.—Dr. Calvin B. Spencer, passed assistant surgeon, U. S. Public Health Service, has been appointed officer in charge of the U. S. Quarantine Station for the port of Baltimore, located at Curtis Bay. He replaced Dr. Le Grand B. Byington, who was transferred to the plague laboratory of the service at San Francisco.

State Medical Election.—Dr. Edward P. Thomas, Frederick, was chosen president of the Medical and Chirurgical Faculty of Maryland at its annual meeting in April, to take office January 1, and Dr. Richard T. Shackelford, Baltimore, was chosen secretary. The latter will succeed Dr. Walter D. Wise, Baltimore, who has been secretary since 1931. The 1940 session will be in Baltimore April 23-24.

MICHIGAN

Personal.—The Wayne County Medical Society, Detroit, held a memorial session at its recent annual meeting in honor of the late Dr. George E. McKean, who served as president and as a trustee. A portrait of Dr. McKean, painted by Roy Gamble, was unveiled. Dr. Alexander W. Blain delivered the dedicatory address.——Dr. Paul W. Bloxsom, Grand Rapids, has been appointed one of Kent County's two coroners, succeeding the late Dr. Harmon C. Wolfe. Dr. Simeon LeRoy, Grand Rapids, is the other coroner.——Dr. William E. Shackleton has been appointed chief of the medical staff at Borgess Hospital, Kalamazoo.

Society News.—Mr. William J. Burns, executive secretary, state medical society, discussed "Legislative Accomplishments and Group Health Service" before the Calhoun County Medical Society, Battle Creek, June 6.——The Flint Business and Professional Women's Club was recently awarded a memorial trophy, presented each year to the Michigan organization promoting the best educational campaign during cancer control month. The award is made through the state unit of the American Society for the Control of Cancer.——Dr. John J. Corbett, Detroit, addressed the Jackson County Medical Society, Jackson, May 16, on "The Injection versus the Operative Treatment of Hemorrhoids."

MINNESOTA

Orthopedic Club Observes Fifteenth Anniversary.—The Minnesota-Dakota Orthopedic Club celebrated its fifteenth anniversary at the Gillette State Hospital for Crippled, St. Paul, May 5-6. The program consisted of an operative clinic and the presentation of cases. Originally called the Minnesota Orthopedic Club, the name was amended in 1934 to include physicians in North and South Dakota. Meetings are held alternately at Duluth, Rochester, St. Paul and Minneapolis.

MISSOURI

Physician Honored.—Dr. Harvey L. Cunningham was guest of honor at a dinner April 10 given by the Cape Girardeau County Medical Society in recognition of his completion of fifty years in the practice of medicine. Principal speakers were Drs. Frederick E. Woodruff, St. Louis, and George W. Walker, Cape Girardeau. Dr. Cunningham was presented with a metal desk set holding two pens, a clock and a gold plate bearing the inscription "To Dr. H. L. Cunningham with the compliments of the Cape Girardeau County Medical Society to commemorate fifty years of service to humanity in the practice of medicine."

NEW JERSEY

Society News.—Dr. Henry J. Tumen, Philadelphia, addressed the Cumberland County Medical Society in April on "Management of Duodenal Ulcer" and Dr. Arthur W. Bingham, East Orange, chairman of the commission on maternal welfare of the Medical Society of New Jersey, spoke on antepartum care as related to maternal mortality.——Dr. Charles A. Flood, New York, among others, addressed the Passaic County Medical Society, Paterson, recently on "Results of Medical Care in the Treatment of Peptic Ulcer."

NEW YORK

Lake Keuka Meeting.—The annual meeting of the Lake Keuka Medical and Surgical Association will be held June 22 at Keuka College, Lake Keuka. Among the speakers will be:

Dr. Martin S. Kleckner, Allentown, Pa., Facts and Fallacies Regarding Proctologic Diseases.
Dr. Stuart B. Blakely, Binghamton, The Psychology of Pregnancy.
Dr. Carlyle N. Haines, Sayre, Pa., Uses and Dangers of Sulfanilamide.
Dr. Louis Emmitt Brown Jr., Sayre, Pa., Uses and Dangers of Sulfapyridine.
Drs. Samuel T. Marshall and Richard B. Cattell, Boston, Surgical Management of Gastric Lesions.
Drs. Harry M. Murphy and Fraser D. Mooney, Buffalo, Gastroscopy and Its Diagnostic Value.

Jail Inmates Exposed to Smallpox.—Health officers are reported to be conducting a wide search for 196 persons released from the Onondaga County Penitentiary, Jamesville, since May 11, all of whom were exposed to a man with smallpox committed that day. The last known addresses of the 196 prisoners covered twenty-two states, it was said. One former prisoner located on the Onondaga Indian Reservation broke out with the disease and vaccination of the entire population of the reservation was undertaken. In addition to the prisoners released, 136 were transferred to other institutions. Eleven cases developed at the jail and other cases in the surrounding area among guards and other persons in direct contact with the institution.——Sixteen cases of smallpox have developed in four towns in Chautauqua County: Ripley, Sherman, Westfield and Mina, the state health department reported May 26. Schools in Ripley were closed and vaccination clinics were set up in the school houses. Up to May 25 3,000 persons had been vaccinated. It was reported that none of the persons who had contracted the disease had ever been vaccinated. This outbreak was traced to a truck driver who traveled between Syracuse and Cleveland. It was reported June 1 that a woman who had visited in Ripley contracted smallpox after she returned to her home in Pennsylvania.

New York City

Syphilis Infrequent Among Marriage Applicants.—An analysis of blood tests required of applicants for marriage licenses from July 1, 1938, when the law went into effect, through December 31, reveals that less than 1 per cent of those examined had syphilis, the New York City Department of Health reports. Premarital blood tests were made on 58,903 persons with positive results in 559, or 0.95. Of the total number 52,585 tests were made by health department laboratories. When the applicants were classified into whites and Negroes, the percentage of infection among the whites was 0.61 and among the Negroes it was 9.82. In 4,386 cases the color was not stated. Among the 559 positive tests 319 were in men and 240 in women.

Medical Information for Fair Visitors.—The five county medical societies of New York, in cooperation with the department of hospitals and the Greater New York Hospital Association, have arranged a special medical-hospital information service for World's Fair visitors from out of town who may need medical or hospital care and may not know where to turn for professional advice or attention. The plan is to establish an information office in each borough telephone office. A call to the office will be answered with a list of reputable physicians nearest the residence of the person calling. Cards bearing this information and the telephone numbers to be called will be distributed to out of town visitors or places where information about the fair is made available.

OHIO

Personal.—The Hempstead Academy of Medicine gave a surprise party recently for Dr. John W. Obrist, Portsmouth, in honor of his completion of fifty years of practice and presented him with a gold-headed cane.——Dr. and Mrs. Stanton Heck, Salem, celebrated their fortieth wedding anniversary and Dr. Heck's fiftieth anniversary in the practice of medicine with a reception at their home April 2. Dr. Heck graduated from the Medical College of Ohio, Cincinnati, in 1889.——The American Society of Clinical Pathologists at its annual meeting in St. Louis May 13 conferred its Burdick Award, a gold medal given annually for an outstanding contribution to medical science, on Dr. Harry Goldblatt, professor of experimental pathology at Western Reserve University School of Medicine, Cleveland. The award was in recognition of Dr. Goldblatt's research on hypertension and diseases of the kidneys.

OKLAHOMA

State Medical Meeting and Election.—Dr. Henry H. Turner, Oklahoma City, was chosen president-elect of the Oklahoma State Medical Association at the annual meeting in Oklahoma City, May 1-3; Dr. Walter A. Howard, Chelsea, was installed as president. The house of delegates voted to establish headquarters of the association in the Plaza Court Building, Oklahoma City, with Mr. R. H. Graham, executive secretary, in charge. An editorial board was elected for the association's journal, composed of Drs. Ned R. Smith, Tulsa; Lewis J. Moorman, Oklahoma City, and Leonard S. Willour, McAlester. Dr. Willour remains as secretary-treasurer-editor. Guest speakers who addressed general scientific meetings were:

Dr. Joseph F. Hamilton, Memphis, Tenn.: Peripheral Vascular Disease, Diagnosis and Treatment; Pseudomycotic Leg Ulcers.
Dr. William Wayne Babcock, Philadelphia: Surgery of the General Practitioner; Intestinal Malignancy.
Dr. Austin A. Hayden, Chicago: The Democracy of American Medicine.
Dr. Edward N. Smith, Oklahoma City: Toxemias of Late Pregnancy.

The Oklahoma Pediatric Society held its meeting Monday May 1 with Dr. Philip C. Jeans, Iowa City, as guest speaker on "Nutrition of the Infant and Child."

PENNSYLVANIA

Seminar at Danville.—*A postgraduate seminar was presented at Geisinger Memorial Hospital, Danville, May 10 under the auspices of the Montour County Medical Society, Danville. Dr. Harold L. Foss and his associates conducted operative clinics, which were followed by a program of papers and demonstrations. Guest speakers were Drs. George Crile Jr., Cleveland, on "Diagnosis and Treatment of Jaundice"; Harold G. Wolff, New York, "Headache," and Frederick A. Coller, Ann Arbor, Mich., "Some Chemical Aspects of Preoperative and Postoperative Care."*

Philadelphia

Schireson Indicted by Grand Jury.—The *Philadelphia Inquirer* reported June 9 that Henry J. Schireson, self styled plastic surgeon who formerly operated in Chicago, was indicted by a federal grand jury June 8. He was charged with concealing $130,000 in assets while filing a petition for voluntary bankruptcy in 1937. It was stated that he employed three aliases and that he swore his assets amounted to only $334. He was also indicted on a perjury charge arising out of the fact that he testified before the bankruptcy referee that he was not married and that he did not live in Merchantville, N. J., a suburb of Philadelphia, the *Inquirer* said. The indictment asserts that Schireson is married and that he lives in Merchantville, according to the newspaper story.

Society News.—The Philadelphia County Medical Society devoted its meeting May 24 to "Health of the School Child" and invited the public. Dr. Edward J. G. Beardsley made a talk on health; Mr. Charles Kurtzhaltz, director of the Philadelphia Health Council and Tuberculosis Committee, spoke on "How the Public Health Is Protected" and a sound film sponsored by the health council, "Body Defenses Against Disease," was shown. Dr. Myer Solis-Cohen, chairman of the committee on public relations, awarded prizes in a health poster contest. ——Dr. Oscar Mercier, Montreal, Canada, addressed the Philadelphia Urological Society May 22 on "Surgical Management of the Horseshoe Kidney" and showed a film on "Surgical Management of Rupture of the Urethra."——Drs. Samuel B. Hadden and Matthew T. Moore, among others, addressed the Philadelphia Neurological Society May 26 on "Neuralgic Headache and Facial Pain" and "Nicotinic Acid and Vitamin B_1 in the Treatment of Multiple Sclerosis" respectively.—— Dr. Bernard L. Wyatt, Tucson, Ariz., addressed the Philadelphia Rheumatism Society May 4 on "Chronic Arthritis: Differential Diagnosis, Special Treatment, Methods, Medical, Orthopedic, Physical Therapy."——Dr. William J. Kerr, San Francisco, delivered a Mary Scott Newbold Lecture of the Philadelphia College of Physicians May 3 on "New Approach to the Etiology and Treatment of Angina Pectoris."

TENNESSEE

Society News.—Dr. Henry M. Goodyear, Cincinnati, delivered the "Foundation Lecture" in otolaryngology at the recent annual meeting of the Tennessee Academy of Ophthalmology and Otolaryngology in Jackson on "Points of Practical Interest in the Diagnosis, Time of Operation and Treatment, in Acute and Chronic Ear Conditions, Including Mastoid, Lateral Sinus, Labyrinth, Meningeal and Petrous Infection." Dr. Virgil G. Casten, Boston, delivered the "Foundation Lecture" in ophthalmology on "Disturbances of Motility and of Visual Fields."

——Drs. Hollis E. Johnson, John C. Burch and Samuel C. Cowan addressed the Nashville Academy of Medicine and Davidson County Medical Society, Nashville, May 30, on "Management of Tuberculosis Complicating Pregnancy."—— At a meeting of the Dyer, Lake and Crockett Counties Medical Society May 3 the speakers, all of Memphis, were Drs. Dick C. McCool, on "Metrazol and Insulin Shock Treatment in Certain Mental Diseases"; Raphael Eustace Semmes and Francis Murphey, "When to Suspect a Brain Tumor."

WASHINGTON

Society News.—The King County Medical Society was addressed May 15 among others by Drs. James F. Blackman on "Bronchoscopic Aspiration of Mucus After Operation" and Oscar S. Proctor, "Extrapleural Pneumothorax and Oleothorax." A symposium on anesthesia was presented before the society April 17 by Drs. Arthur O. Tucker, George R. Marshall and William A. Millington. Dr. William G. Cameron, Tacoma, discussed legislative news.——Dr. Joel W. Baker, Seattle, addressed the Spokane County Medical Society, Spokane, April 13 on "Surgical Considerations in Carcinoma of the Rectum and Rectosigmoid Junction."

WISCONSIN

Annual Conference of Secretaries.—The annual conference of the secretaries of county medical societies was held in Madison April 23. The speakers were Dr. Albert E. Rector, Appleton, president of the State Medical Society of Wisconsin, on the work of the society; Mr. George B. Larson, assistant secretary of the state society, on voluntary insurance plans now on trial in Wisconsin; Dr. James C. Sargent, Milwaukee, on hospital insurance; Dr. Dexter H. Witte, Milwaukee, on "Speaking Before the Public"; Mr. J. George Crownhart, secretary of the state society, legislation affecting the public health, and Dr. Rock Sleyster, Wauwatosa, now President of the American Medical Association.

Society News.—Dr. Frederick A. Figi, Rochester, Minn., addressed a joint meeting of the Winnebago County medical and dental societies in Oshkosh May 4 on "Malignant Diseases of the Mouth."——Dr. Harold E. Marsh, Madison, addressed the Columbia-Marquette-Adams County Medical Society, Portage, May 16 on "The Chemotherapy of Pneumonia."——Drs. Frederick H. Falls, Chicago, and Mabel G. Masten, Madison, addressed the Dane County Medical Society, Madison, May 9 on "Abortion" and "Polyneuritis of Pregnancy" respectively. ——At a meeting of the Brown-Kewaunee-Door County Medical Society, Green Bay, May 11 the guest speaker was Dr. Ovid O. Meyer, Madison, on "Treatment of Anemias."——Dr. Howard W. Haggard, New Haven, Conn., recently addressed the Douglas County Medical Society, Superior, on problems confronting the medical profession.

GENERAL

Special Society Elections.—Dr. Allen O. Whipple, New York, was elected president of the American Surgical Association at its recent annual meeting and Dr. Charles G. Mixter, Boston, was reelected secretary. The 1940 session will be in St. Louis.——Dr. John MacK. Brown, Los Angeles, was chosen president-elect of the American Laryngological, Rhinological and Otological Society at its annual meeting in May and Dr. Lee M. Hurd, New York, was inducted into the presidency. Dr. Carlton Stewart Nash, Rochester, N. Y., is the secretary. New York was tentatively selected as the place for the 1940 session.——At the annual meeting of the American Association of the History of Medicine in May Dr. Esmond R. Long, Philadelphia, was elected president to take office January 1. Dr. Henry E. Sigerist, Baltimore, is the secretary. The next annual session will be in Atlantic City, N. J., May 4-5.

Board of Obstetrics and Gynecology.—The American Board of Obstetrics and Gynecology announces that 228 of 259 candidates examined in St. Louis May 13-16 were certified, twenty-nine failed and two did not finish the examination. Because of increased expenses of administration the board found it necessary to increase the application and registration fees to $15 and $75 respectively. The board also announces that henceforth it will hold only one Group B, Part I examination a year. The next Part I examination will be held in various cities of the United States and Canada December 2. Applications for this examination must be filed not later than October 4 with the secretary. The general oral and pathological examinations for all candidates (groups A and B) will be conducted by the entire board in Atlantic City, N. J., June 7-9, 1940. Applications for admission to Group A, Part II examinations must be on file not later than March 15, 1940, in the secretary's office. For further information and application blanks address Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh.

Pacific Coast Oto-Ophthalmological Society.—The twenty-seventh annual meeting of the Pacific Coast Oto-Ophthalmological Society will be held at the Fairmont Hotel, San Francisco, June 19-22, under the presidency of Dr. Frederick C. Cordes, San Francisco. Included among those presenting papers will be:

Drs. Cordes and Michael J. Hogan, Hemangiomatosis Retinae (Von Hippel's Disease): Report of a Case Treated by X-Ray.
Dr. Henry P. Wagener, Rochester, Minn., The Significance of Spasm in Retinal Arteriolar Disease and in Retinitis.
Dr. Otto M. Rott, Spokane, Wash., Method of Procedure in the Diagnosis of Otitic Intracranial Complications.
Dr. LeRoy A. Schall, Boston, Diagnosis and Treatment of Cancer of the Upper Respiratory Tract.
Dr. Howard E. Carruth, Portland, Ore., The Evisceration Operation—A Modification.
Dr. Irving M. Lupton, Portland, Clinical Observations in the Treatment of Acute Streptococci Otitis Media During Sulfanilamide Therapy.
Dr. Carroll L. Smith, Spokane, Lymphocytoma.
Dr. Carl D. F. Jensen, Seattle, Sympathetic Ophthalmia Complicating Cataract Extraction.

The program also includes four courses each in ophthalmology and otolaryngology.

Annual Health Awards to Cities.—Cleveland won the first award for cities of over 500,000 population in the annual city health contest for 1938 sponsored by the U. S. Chamber of Commerce in cooperation with the American Public Health Association. Winners in the other population groups were: 250,000 to 500,000, Providence, R. I.; 100,000 to 250,000, Grand Rapids, Mich.; 50,000 to 100,000, Newton, Mass.; 20,000 to 50,000, Plainfield, N. J., and less than 20,000, Englewood, N. J. Special awards were given to Baltimore; Brookline, Mass.; Detroit; Greenwich, Conn.; Hackensack, N. J.; Hartford, Conn.; Newark, N. J.; New Haven, Conn.; Pasadena, Calif.; Syracuse and Schenectady, N. Y. Each of these has previously won first awards and maintained its high standards in 1938. The rural health contest, which is financed by the W. K. Kellogg Foundation of Battle Creek, Mich., resulted as follows: Northeastern division, Cattaraugus County, N. Y.; Eastern division, Wicomico County, Md.; Southeastern division, Charleston County, S. C.; North Central division, Gallatin County, Mont.; Western division, Los Angeles County, Calif. In a special contest for tuberculosis control Hartford, Conn., and Newton, Mass., tied for first place and New Haven received an award of merit. In a similar contest for syphilis control Louisville, Ky., was the winner. Numerous awards of merit were also conferred. These awards are made not necessarily to the healthiest communities, it was pointed out, but for the effectiveness with which a community is meeting its health problems.

FOREIGN

Prize for Orthopedic Work.—Competition for the Umberto I. Prize was opened by the Rizzoli Orthopedic Institute of Bologna, Italy, January 1 and will close December 31. The prize is offered for the best "work or invention in orthopedics." Foreign as well as Italian scientists are invited to take part, according to an announcement. Application for information should be made to the president of the Rizzoli Institute, Bologna.

Courses in English in Paris.—The Faculty of Medicine of Paris, the Association for Improvement of Medical Relations and the American Medical Society of Paris have organized a series of courses to be given in English by medical authorities in various hospitals in Paris during May, June and July. A program of the courses may be obtained by writing to the Faculty of Medicine or the American Medical Society, care of the American Hospital of Paris, 63, Boulevard Victor-Hugo, Neuilly-sur-Seine.

Course in Malariology.—The Institute of Malariology in Rome is offering a course in malariology July 25 to September 20. Among the subjects to be covered are: hematology, protozoology, malaria parasites and microscopic diagnosis, pathology of malaria, clinical study of malaria, entomology, epidemiology of malaria and malaria prophylaxis. There will be practical work and laboratory demonstration, a survey of a malarious area, visits and residence in experimental stations and in a center of induced malaria. The course is open only to graduate physicians.

Foreign Letters

LONDON

The Medical Profession Prepared for an Emergency

In previous letters it has been stated that a national register of physicians, comprising 95 per cent of their number, who will be available for the various branches of medical work in the event of a national emergency has been compiled by the Central Emergency Committee of the British Medical Association. This committee has now been reconstituted so as to make it representative of every branch of medical practice. Having prepared plans for the utilization of the profession, it will be the instrument for putting them into operation if the emergency should occur. In every division of the British Medical Association a local emergency committee has been established and is supplied with a copy of the local section of the national register. This committee will deal with all questions of medical personnel referred to it and will consult representatives of medical insurance committees, local authorities and voluntary hospitals. All requests for medical personnel from the military services or other government departments will be made to the Central Emergency Committee. The earmarking of practitioners for local duties, such as first aid posts, has been done by the local committees provisionally but had to be confirmed by the central committee. Consultants and specialists on the staffs of the London hospitals will be earmarked by a special committee of the Royal Colleges of Physicians and Surgeons. Pathologists will be dealt with by a subcommittee of the central emergency committee and the Medical Research Council. Physicians engaged predominantly in scientific work will be dealt with by a committee of the Royal Society in cooperation with the Central Emergency Committee.

Practitioners employed in time of war for whole time service in hospitals for the treatment of casualties will be paid $2,500 a year plus an allowance of $500 if board and quarters are not provided. An additional $2,500 may be paid to those in a supervisory capacity, whether as a medical superintendent of a hospital containing more than 500 beds or as a specialist controlling a department. Medical officers placed in positions of greater responsibility may receive remuneration up to $7,500 per annum. Services at first aid posts will be paid at the rate of $6 for a session of two hours or $12 for a longer period in any one day.

Surgery in Old Age

At the section of Surgery of the Royal Society of Medicine the president, Mr. C. H. S. Frankau, opened a discussion on surgery in old age. He pointed out that age was not merely a question of years but depended on degenerative processes associated with a diminished blood supply. The saying "A man is as old as his arteries" would be more accurate if it embraced the heart muscle. Injury to the soft parts might be disproportionately serious in the aged. Severe bruises must therefore be treated with caution; all pressure should be avoided and after from twenty-four to forty-eight hours an electric pad applied intermittently was often of value. But intense heat or cold (such as an icebag) might precipitate gangrene. Open wounds were more liable to infection, and healing was slow.

FRACTURES

It was not true to say that fractures in old persons united slowly or not at all, excepting intracapsular fracture of the neck of the femur. Most cases of Colles fracture gave good results if properly reduced and immobilized. In fractures of the long bones union was delayed but eventually complete. Fractured patella in the old was often considered unsuitable for treatment. But why condemn a man of 70 to the life of a cripple when removal of his patella would give him a useful limb? Another side of the picture was the unpredictable and unexplained phenomenon of disunion occurring some weeks after apparent healing of a fracture. In plaster treatment, pressure sores over bony points must be prevented by careful padding. Massage he regarded as not only valueless but dangerous to old persons, owing to liability to dermatitis, which might lead to subcutaneous venous thrombosis.

ACUTE ABDOMINAL CONDITIONS

Acute appendicitis in old age might resemble intestinal obstruction of slow onset with an "acute indigestion" pain commonly referred to the epigastrium, rarely to the right iliac fossa, with a persistent pyrexia. Physical signs were indefinite and the abdomen was distended. Sometimes there was visible peristalsis, and tenderness was general and greatest in the hypogastric and umbilical regions. At operation there was little peritoneal exudate, the intestine was sticky and red, and the appendix was rarely shut off by adhesions. These patients tolerated operation well. Another type presented "an acute attack of indigestion" followed by inability to take food, constipation or diarrhea and persistent slight pyrexia. Examination was indefinite at first but later revealed a hard tender mass in the right iliac fossa (appendical abscess). The abscess formation was remarkably slow. As in all cases of appendical abscess, operation should be delayed until localization was complete, and if the appendix was not found at once it should not be sought.

For short attacks of biliary colic surgery was not advisable, provided they were controlled by morphine and atropine and provided the gallbladder was not persistently distended. But if the attacks increased in frequency or severity or the gallbladder became distended, operation was inevitable. Unless it was "hanging by a pedicle," drainage was preferable to removal.

CARCINOMA

Carcinoma in the old usually progressed slowly with less tendency to disseminate. In the breast, removal of the gland was usually adequate; in the colon, exclusion by anastomosis was safer than excision; in cancerous pyloric stenosis, gastroenterostomy was the most that should be done. In the discussion Mr. V. Z. Cope maintained that carcinoma of the stomach should be removed whatever the age. He had operated successfully on a patient of 78.

The Frequency of Blood Donation

How often may a donor give blood without harm to himself? The report that the unanimous opinion of the staff of the General Infirmary of Leeds that "to give blood more than once in six months is harmful to the donor and not of maximum help to the patient" has led to a rejoinder from Dr. H. F. Brewer, medical officer to the British Red Cross Society London Blood Transfusion Service. In these days when volunteering for blood donation in a time of national emergency may be required on a large scale he feels that such a statement should not pass unchallenged, as it is contrary to experience in this and other countries. He states (*Brit. M. J.* **1**: 895 [April 29] 1939) that at present the London Blood Transfusion Service has 2,698 donors, of whom 630 are Rover Scouts (the youngest age of acceptance is 18 years). The established minimum safe interval is three months for males and four months for females, and the majority of donors give blood at these intervals. In an experience of eight years' medical supervision of the London Blood Transfusion Service, Dr. Brewer has found that such frequency in no way impairs health and indeed provides a margin of safety. Periodic hemoglobin

estimations of donors after the usual bleedings (from 400 to 750 cc.) shows a constant return to the normal figure within two months. Since the end of 1931, 1,076 members of the service who have given blood on ten or more occasions (a few up to fifty) at such intervals have been examined and these include fifty Rover Scouts. The examinations were carried out less than three months after the last bleeding. It was found that health was in no way impaired or any degree of anemia produced.

Changes in the Medical Profession

The medical profession in Austria has been completely adapted to conditions in the "old empire," that is Germany, since the beginning of 1939. The changes have been significant both in private and in sick fund (krankenkasse) practice. With the elimination of about 2,000 Jewish physicians, a considerable number of men, mostly young physicians, have established themselves here, many from Germany, a fact to which the public has yet to get used. In the hospitals the overwhelming majority of the attending physicians are quite young; some have not even graduated but are in the last semesters of their studies. Many former heads were discharged. Some hospital departments were discontinued. The sick fund practice was also completely reorganized and adapted to the German model. The physicians are paid on the basis of a system of points complemented by a system of number of heads in the allotted territory for each physician. Payment is not high as a rule; however, in the case of extremely busy physicians the income is considerable. In districts inhabited by poor people, the practicing physician has a guaranteed minimum of 500 marks monthly; to this is added extra pay for every child of the physician. This system of increasing the family is commendable. A definite amount is granted for the first and second child, this is doubled for the third child and the amount increases again with the fourth and with the fifth child. At the same time the income tax becomes progressively smaller. The introduction of medical attention on Sundays is of special importance for the public. In every district about 10 per cent of the residing physicians, including specialists, are at the disposal of private and sick fund patients from Saturday evening to Monday morning. Their names and addresses can be had in every pharmacy and police station. The Pharmacopeia Germanica, which has been introduced into Austria, differs somewhat from the Pharmacopeia Austriaca. Especially important changes have been made for the prescription of cocaine and morphine and their derivatives. Every physician is obliged to keep a "cocaine" and a "morphine" book, in which each prescription containing cocaine or morphine has to be recorded. Narcotics prescribed for the physician's own use have to be recorded also. The prescribed quantity must not exceed 0.1 Gm. for cocaine and 0.2 Gm. for morphine per patient daily. Precise rules regulate prescriptions for addicts. These limitations do not apply to ethylmorphine hydrochloride, codeine, pantocain, eucaine and tutocain. Many drugs that are bought in Germany have become much cheaper on account of the abolition of customs. Pharmacists' taxes, on the other hand, have become higher. Drug prices have become lower on the whole, but physicians' fees have increased somewhat; in return physicians have to pay higher taxes than formerly, since control became more precise and the taxes were raised. As far as one can judge, the average income of Aryan physicians has increased somewhat. The position of still active Jewish physicians is becoming steadily worse because the number and paying ability of Jews is constantly decreasing and such physicians may treat Jewish patients only.

Physical Condition of Young Men in Austria

An article by the army medical officer Müller in the latest issue of the *Aerzteblatt für Oesterreich* gives information on the physical condition of men born in 1917 and 1918. Both volunteers and conscripts of this class reported for mustering. In Austria 4⅔ per cent of the conscripts were on the border of the admissible stature of 154 cm., in the old empire 3.9 per cent. The proportion of dental caries in need of immediate treatment was 33 per cent in Austria and 25 per cent in the old empire. Diseases of the digestive apparatus were far more frequent in the first group. These diseases may be responsible for the greater frequency of general bodily weakness at this age in Austria (7 per cent against 3 per cent). Consequences of finger injuries, such as crooked or stiff fingers, were likewise much more frequent, perhaps on account of poorer accident prevention. The frequency of goiter in Austria is known; 16.7 per cent of the men in this class had it against 7.54 per cent in the old empire, mostly in earlier stages to be sure, without disturbances of health. Examination of the young men on the basis of profession is of interest. Of all classes examined in Austria, 30.77 per cent were engaged in farming and forestry. Of these men 68 per cent were found in completely good health; men in these professions showed the lowest health percentage. Of the metal workers, 81.55 per cent of the men were in completely good health. The average for Austria was 75 per cent of all men mustered. These figures have but conditional value, as in 21 year old men we need not yet look for a reaction to professional activity, while in 32 year old men the reactions may have become quite marked.

The Constancy of Jewish Racial Characteristics

Dr. Walzel organized an exhibition on "the physical and psychic appearance of the Jews" in the department of anthropology of the Naturhistorisches Museum of Vienna. The exhibition serves scientific rather than propaganda purposes, although some parts of it will not pass the test of severe scientific criticism. On display are illustrations from the time of the Roman emperors, illustrations of monuments in the Near East and recent photographs from the police headquarters of Vienna, obtained in the course of official investigations and displayed with or without the consent of those concerned. On the basis of these illustrations one may conclude that the characteristics of the Jews have not changed essentially in the last 3,000 years. Among these characteristics are the "half-moon" profile, the "duck bill" profile, the "parrot" nose, the "6" shaped nose, the curved lower rim of the eyelid and the lip forms. The illustrations of the Antropologisches Institut show clearly defined characteristics passing from parents to children. Although examination of the blood has shown no fundamental difference between Germans and Jews, there is probably some difference in the incidence of certain constitutional diseases (diabetes, leukemia, obesity). Psychic diseases apparently permit certain differentiations also, yet there are no exclusively "Jewish diseases." Fluctuations in body size, furthermore, may have been for many years just as constant with Jews as with Germans and depend on the same factors: environment, food and ways of living. An interesting illustration shows finally that the German legislators' laws for the "protection of the German blood" do not differ in essence from the ancient laws of the Jews for the preservation of the Jewish people.

Death of Professor Finger

Prof. Ernest Finger, former university professor of dermatology and syphilology, died recently at the age of 83. He had been a pupil of Professor von Siegmund and was head of the Klinik für Syphilidologie und Dermatologie of Vienna in the Allgemeine Krankenhaus from 1904 to 1927. Professor

Finger acquired a prominent position through his clinical work, which he carried on in true humanitarian spirit, and his textbooks have been translated into various languages. He did great work in starting the fight against venereal diseases in Austria in 1907 and brought highly practical help through promoting therapy in his own treating stations in Vienna and the Austrian provinces. He brought help of special value through his "evening ambulances." His services came into full play in later years through a large scale organization for finding the sources of infection, as well as through general enlightenment of the population about the dangers of venereal diseases. As a pioneer he will live in the history of medicine.

Death of Professor Schaffer

Prof. Joseph Schaffer died recently in Innsbruck at the age of 79. He gained renown fifty years ago through his researches in microscopic anatomy and histology. He was appointed head of the Histologisches Institut of the University of Vienna and founded in Vienna, with Dr. Ebner von Rofenstein, the well known Histologische Schule, from which institution were appointed the best known representatives of this branch of science to the universities of Central Europe. His textbook on histology was translated into many languages. For the last twenty years Schaffer devoted himself to the study of cutaneous glands in mammals.

ITALY

(From Our Regular Correspondent)

May 15, 1939.

Annual Congress of Surgery

The Società italiana de Chirurgia recently held its annual reunion in Rome with Prof. Roberto Alessandri as president.

SUPPURATION AND GANGRENE OF LUNG

Prof. Raffaele Paolucci spoke on suppuration and gangrene of the lung. According to the speaker the old formula "ubi pus ibi evacua" stands for suppuration of the lung. However, frequently the abscess is spontaneously evacuated through the bronchi. Medical treatments, physical therapy and bronchoscopy aim to stimulate spontaneous evacuation of pulmonary abscess but the treatments have no specific value. Medical treatment is continued if there is a tendency to spontaneous cure of the abscess. The patient is observed by the physician in collaboration with the bronchoscopist, the roentgenologist and the surgeon. The mortality rate after operation in the acute forms is 15 per cent and in the chronic forms it is about 50 per cent. As a rule, simple acute abscesses are cortical; they can be controlled by simple pneumonectomy or pleurotomy and end in recovery of the patient in 100 per cent of the cases. Putrid acute abscesses are treated by tamponage followed by resection of the parietal lid of the abscess in almost all cases. The operation induces cure of the abscess in 85 per cent of the cases. In 3 per cent the abscess can be cured by tamponage without parenchymal operation. Lobectomy or progressive resection of the involved parenchymal zone is indicated in chronic suppuration. The mortality rate in these cases is about 50 per cent. Massive gangrene develops in about 4 per cent of the cases and does not yield to either medical or surgical treatment. Perforation of a putrid abscess into the pleura is extremely grave. Exploratory punctures, transthoracic parenchymal injections of drugs and artificial pneumothorax are contraindicated in suppuration of the lung. Artificial pneumothorax in the treatment of suppuration frequently causes putrid empyema.

OSTEOMYELITIS

Prof. Raffaele Brancati of the University of Parma spoke on chronic and acute osteomyelitis. Primary hematogenic osteomyelitis of adolescents usually develops at the metaphysis and in adolescents under the age of 14. It is caused by staphylococci of diminished virulence which are carried by histioblasts to the metaphysis. The most important forms of secondary osteomyelitis are those which involve the cranial bones, especially the petrous portion of the temporal bone and the maxillas. The diagnosis of petrositis is made from the appearance of Gradenigo's syndrome (suppurative otitis media and mastoiditis complicated by trigeminal temporoparietal pain and abductor paralysis). Pain in the head of a bone with functional incapacity, fever and leukocytosis in a youth under the age of 15 points to a diagnosis of acute osteomyclitis and it is advisable to place him immediately under the care of a surgeon. In general, the prognosis is better for infants than for older children. There is a tendency to operate in the early stages of the disease. The classic operation consists in opening the metaphysis and the medullary canal and in plugging.

The next congress will be at Naples and the topics will be (1) closed trauma of the abdomen, (2) surgery on the adrenals and (3) treatment of syndromes of the type of Banti's disease.

Meeting of Dermatologists

The Società Italiana di dermatologia e sifilografia met recently at Palermo with Professor Flarer as president.

Professor Tommasi of Palermo University spoke on a treatment for metasyphilis which he has used since 1931. The treatment consists of administration of antirabic vaccines either fresh or prepared with phenol. They are given to the patients by means of serial vaccinations, which are followed by intramuscular injections of acetarsone or by intravenous injections of arsphenamine in large doses. The treatment is harmless, nonpyretogenic and well tolerated. Dr. Cottini of Bonn carried on experiments with Tommasi's treatment and compared the results with those obtained from chemical pyretotherapy. He found that the administration of rabic vaccines induces diminution of the size of the syphiloma and of the number of spirochetes in experimental syphilis in rabbits, whereas chemical pyretotherapy has no action on experimental syphilis. The speaker has used the treatment for the last eight years in forty cases. He obtained immediate satisfactory results from the treatment in twenty-four cases of the group of forty. In twelve of the twenty-four cases, late results showed complete control of the disease. Antirabic vaccines give the same percentage of satisfactory results as the Wagner treatment.

Professors Malfa and Bosco reported the results of studies for ascertaining the influence of roentgen irradiations of the spleen on serologic tests for syphilis. The speakers observed that reactions which are negative or slightly positive before the application of roentgen irradiations on the spleen become positive or increase in positivity after them. According to the speakers, roentgen splenic irradiations can be used as a test for actual control of syphilis.

Professor Coppolino was able to identify aerophilic and aerophobic types of gonococcus from menstrual blood. Menstruation does not interfere with the vitality of the gonococcus. Because of the fact that gonorrhea in women is spontaneously reactivated during menstruation, cultures of menstrual blood, which is taken during the first few days of menstruation, are of diagnostic value in gonorrhea in apparently normal women. Such cultures are also of value in making a diagnosis on the recovery of the patients from the disease.

DERMATOLOGY

Professor Tommasi discussed the value of Reenstierna antiserum in the treatment of leprosy. The antiserum is prepared by inoculating sheep with glycerin bouillon cultures which contain acid fast and non-acid fast forms of mycrobacterium of leprosy. New and old cultures and the toxins and products of disintegration of the bacilli are used. The speaker gave the treatment recently to three lepers. The serum has a favorable effect on the ulcers but none on the further general evolution of the disease.

Professor Monacelli reported the results obtained from chemotherapy in a group of lepers at the leprosarium of Messina. Rubrophen (trimethyl-dioxy-oxotritan) Sailer's preparation, was the dye used. Satisfactory results have been previously reported from administration of the drug in the treatment of cutaneous and surgical tuberculosis. The drug has a favorable effect on leprosy. The symptoms and general condition of the patient improve. Toxic phenomena have been observed in some cases which show the advisability of carrying on further work, especially for determination of the proper dose.

Professor Flarer spoke on atabrine as local treatment of oriental sore. He obtained satisfactory results in fifty cases of a new series.

Professor Petronici reported satisfactory results from benzyl benzoate in the treatment of scabies. He resorted to the treatment in 648 cases and found that it has a rapid action on scabies without inducing unpleasant secondary reactions. The technic is simple and the method is economical.

BUCHAREST

(From Our Regular Correspondent)

April 17, 1939.

The State of Public Health in Rumania

While Rumania endeavors to keep pace with western civilization, little has been done as yet to teach the population how to guard its health. Although the urban population is well cared for, the rate of physicians to the population being, in general, 1:400, private practitioners are scarce in the rural districts because the peasants are unaccustomed to pay for medical service and the villages consequently offer little attraction for young practitioners. There are rural districts where the rate is one physician to 25,000 people. Official physicians having under their care such large areas cannot possibly give good medical service. While the birth rate is favorable in some regions, many of the babies die before the age of 1 year. In the last five years there has been an improvement in this respect because of the employment of well trained midwives and an increase in the number of qualified physicians.

The ministry of public health has provided for every county hospital (there are seventy-six in all) an epidemic section. In recent years arrangements have been made for the dispensaries in the villages to have special rooms for patients with epidemic diseases. It is planned to establish this year from 150 to 200 more dispensaries. The rural population will be instructed to appear at these dispensaries at the very beginning of their illness.

The population of Bessarabia, chiefly because of bad customs and habits, is not very cleanly. Men generally wear dark shirts, unchanged even for a month. It is no wonder that they become infested. In the last two years, forty delousing detachments have been at work. The late minister, M. Costinescu, sent 100 young physicians, and others came later, serving their half year of military service, to improve public health and chiefly to institute personal cleanliness. The minister also has sent 40,000 white shirts into this danger zone in order to accustom the people to changing shirts at least once a week. In every Bessarabian village baths and delousing stations were constructed. With these strict hygienic measures, there is some hope that satisfactory health conditions will prevail in Bessarabia.

Malaria is common, especially in Bessarabia, in East Moldavia, in the Danube valley and in Dobrogea. There are villages where eighty of 100 inhabitants suffer from this disease. According to official figures the number of cases of malaria in Rumania is not far from three quarters of a million. It is pitiful to see these debilitated, anemic persons and still more so to see the underdeveloped children. In 1936 an energetic campaign against malaria was conducted in the county of Constanta, between Constanta, a large port, and Mangalia. During 1937 an interministerial conference was held with university professors in the royal palace, conducted by King Carol II, who is a strong supporter of the movement. In the state budget, adequate sums have been allotted for this antimalaria work. The areas most in need are the villages about the city of Jassy, capital of the province of Moldavia. The draining and filling in of the valley of Barla was begun in April 1937 and now is nearing completion.

Another common disease in the villages of Muntenia and Moldavia is pellagra. During the World War the soldiers became accustomed to wholesome food, but little by little they returned to the old custom of selling their wheat and living exclusively on bread made of maize flour. Although there is a goat or cow to almost every house, few people drink milk. The people are instructed what food to eat through the school teachers, who have an opportunity to judge from the children whether the families feed themselves properly. During the summer vacation teachers take postgraduate courses in Bucharest, Cluj and Jassy, but some years are necessary for the 20,000 teachers of the country to receive this training.

Absolutely gratuitous antisyphilitic treatment has been introduced for the indigent. The results are satisfactory. In some districts several years ago the number of stillbirths was frightful, while at present such births occur infrequently.

In certain regions the population enjoys prosperity and nourishing foods. The government regards it a supreme duty to provide for the even distribution of foods in all parts of the country, and it pays great attention to the suppression of profiteering in foods. It is the vogue in Banat, one of the richest provinces of Rumania, to have only one child per family, and the mortality rate far exceeds the birth rate. There are villages where only a few young men can be recruited. This social problem is being solved by the joint action of physicians, the church and the school.

Regulation of Foreign Diplomas

Applications for permission to have validated a foreign diploma have to be sent to the ministry of public education with the following documents enclosed: original diploma, a notarized copy of this diploma, certificate of birth and birth place, a list of the schools and university attended and the official list of subjects studied. The minister of public education then submits the application to one of the Rumanian universities. The applicant has to pay 500 lei to the university. The ministry of public education publishes in the official gazette every month the list of those who have been validated in the preceding month.

Physician Appointed Governor General

King Carol II has appointed Dr. Coriolan Tataru, professor of dermatology at the university of Cluj and president of the National Medical Association, as governor general of Somes province.

Marriages

FRED L. NORTON, Belle Vernon, Pa., to Miss Helen Cooke Patterson of Connellsville, February 21.

WILLIAM K. OWEN to Mrs. Myra Williams, both of Birmingham, Ala., February 26, at Attalla.

ISAAC L. VAN ZANDT, Fort Worth, Texas, to Miss Ruth Boddeker of Galveston, February 11.

EDGAR BRYAN QUARLES, America, Ala., to Miss Ruth Brookins of Gloversville, N. Y., recently.

KARL G. KASTL, Granton, Wis., to Miss Priscilla Jane Richard of Appleton, February 16.

URBAN H. ZEHNPFENNIG, Merkel, Texas, to Miss Modyne Sheppard of Dallas, February 4.

J. WELLINGTON TRUITT, Gainesville, Texas, to Miss Ruth Bounds of Denison, February 4.

Robert George King, New York, to Miss Louise Perkins of New Canaan, Conn., March 25.

WELDON DOAK BLASSINGAME, Fort Worth, Texas, to Miss Helen Shyrock, February 4.

WILLIAM H. GIDNEY, West, Texas, to Miss Lois Cox of Dallas, January 26.

Deaths

Arthur Thoms Jones ⊕ Providence, R. I.; New York University Medical College, New York, 1896; member of the New England Obstetrical and Gynecological Society, New England Surgical Society and the American Urological Association; fellow of the American College of Surgeons; past president of the Rhode Island Medical Society; consulting surgeon to the Memorial Hospital, Pawtucket, St. Joseph's and Miriam hospitals, Providence, Woonsocket (R. I.) Hospital, Westerly (R. I.) Hospital and the South County Hospital, Wakefield; aged 64; died, March 19, of coronary occlusion, pulmonary embolus and arteriosclerotic heart disease.

Edward Morton Heacock ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; fellow of the American College of Surgeons; member of the Radiological Society of North America; on the staffs of the Lutheran Memorial and Evangelical Deaconess hospitals; aged 62; died, March 12, of coronary sclerosis.

Walter Woodley Gosling, Red Bank, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1923; member of the Medical Society of New Jersey; fellow of the American College of Surgeons; on the staffs of the Fitkin Memorial Hospital, Neptune, and the Riverview Hospital; aged 41; died, March 4, of cerebral hemorrhage.

William H. Haughey ⊕ Battle Creek, Mich.; Detroit College of Medicine, 1888; past president and secretary of the Calhoun County Medical Society; was secretary of the council and councilor of the third district of the Michigan State Medical Society; aged 82; died, April 14 of a gallbladder condition following pneumonia.

Charles Edward Glynn ⊕ Davenport, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; served during the World War; aged 66; on the staff of the Mercy Hospital, where he died, March 5, of arteriosclerosis and hypertension.

William W. Gill, Enid, Okla.; Northwestern Medical College, St. Joseph, Mo., 1893; Beaumont Hospital Medical College, St. Louis, 1901; member of the Oklahoma State Medical Association; county superintendent of health; aged 71; died, March 25, of coronary thrombosis.

Elizabeth Taylor Gray, Boston; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1895; member of the Massachusetts Medical Society; formerly on the staff of the New England Hospital for Women and Children; aged 75; died, March 24.

Isaias Alexander Lehman, New York; University of Kharkov Faculty of Medicine, Russia, 1900; member of the Medical Society of the State of New York; on the staff of the Morrisania Hospital; aged 62; died, March 2, in the Bronx Hospital of carcinoma of the pancreas.

Treber Coleman Crawford, Portsmouth, Ohio; Starling Medical College, Columbus, 1897; member of the Ohio State Medical Association; formerly city physician; on the staff of the Portsmouth General Hospital; aged 70; died, March 7, of Parkinson's syndrome and myocarditis.

George Alexander Hartley ⊕ Battle Creek, Iowa; State University of Iowa College of Medicine, Iowa City, 1908; medical director and owner of the Odebolt (Iowa) Hospital and the New Battle Creek Hospital; aged 56; died, March 17, of an overdose of gas taken for pain.

Mary Elizabeth Lawrence, Waterford, Conn.; Boston University School of Medicine, 1893; aged 84; for many years on the staff of the Lawrence and Memorial Associated Hospitals, New London, where she died, March 6, of bronchopneumonia and arteriosclerosis.

Thomas D. Doan, Palmyra, Ill.; St. Louis University School of Medicine, 1905; member of the House of Delegates of the American Medical Association in 1918; member and formerly vice president of the Illinois State Medical Society; aged 70; died, March 1.

Edward Daniel Helfrich ⊕ Columbus, Ohio; Ohio Medical University, Columbus, 1902; member of the American Academy of Ophthalmology and Oto-Laryngology; formerly member of the state legislature; aged 63; died, March 21, of cerebral hemorrhage.

Thomas Jackson Ratliff ⊕ Colorado, Texas; St. Louis College of Physicians and Surgeons, 1897; past president and secretary of the Mitchell County Medical Society; city health officer; formerly county health officer; aged 70; died, February 18.

George Boston Glover, Monticello, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1887; member of the Medical Association of Georgia; aged 77; died, March 27, in a hospital at Thomasville, Ga., of prostatic hypertrophy.

Raymon Herkles Henslee, Winters, Texas; Baylor University College of Medicine, Dallas, 1925; past president and secretary of the Runnels County Medical Society; served during the World War; aged 41; died, March 2, of pneumonia.

James Cook Ayer ⊕ New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; served during the World War; formerly on the staff of the Bellevue Hospital; aged 76; died, March 20.

John David Dean, Birmingham, Ala.; University of Texas School of Medicine, Galveston, 1928; member of the Medical Association of the State of Alabama; aged 34; died, March 25, in the South Highlands Infirmary, of acute polyneuritis.

Jacob Murray Hoskins, Marion, Ohio; Kentucky School of Medicine, Louisville, 1904; member of the Ohio State Medical Association; served during the World War; aged 56; died, March 1, of chronic bronchitis and cardiac hypertrophy.

James Owen Shannon, Franklin, Tenn.; Vanderbilt University School of Medicine, Nashville, 1877; past president and secretary of the Williamson County Medical Society; aged 82; died, February 4, of hypertensive cardiovascular disease.

George Washington Clendenan, Toronto, Ont., Canada; Victoria University Medical Department, Coburg, 1882; at one time mayor of West Toronto and medical officer of health; formerly associate coroner; aged 78; died, March 18.

Fred Raymond Lewis ⊕ Rochester, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1911; on the staff of the Rochester General Hospital; aged 57; died, March 8, of facial erysipelas and bronchopneumonia.

John Curtis Grandstaff, Preble, Ind.; Eclectic Medical Institute, Cincinnati, 1899; member of the Indiana State Medical Association; formerly county health officer and coroner; aged 66; died, March 31, of coronary thrombosis.

Ralph Harold Hertzler ⊕ Newton, Kan.; Northwestern University Medical School, Chicago, 1908; served during the World War; on the staff of the Bethel Deaconess Hospital; aged 52; died, March 30, of coronary sclerosis.

Harry Crittenden Harris, Glen Ridge, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1883; formerly member of the school board and board of health; aged 78; died, March 2, of chronic myocarditis.

Jefferson D. Ratliff, Seymour, Texas; St. Louis College of Physicians and Surgeons, 1901; formerly city and county health officer; aged 77; died, February 24, in a hospital at Wichita Falls of complications of renal stones.

Emil Heller Henning, Baltimore; University of Maryland School of Medicine, Baltimore, 1908; formerly health officer in the public school division of the city health department; aged 58; died, March 4, of Hodgkin's disease.

John Clarence Kelly, Mitchell, Ind.; College of Physicians and Surgeons, Baltimore, 1882; aged 80; died, March 10, in the Homeopathic Hospital, Wilmington, Del., of carcinoma of the tonsil with abdominal metastasis.

George Franklin Edmunds, Bristol, Vt.; Baltimore Medical College, 1892; member of the Vermont State Medical Society; aged 76; died, March 18, in the Bradenton (Fla.) General Hospital of arteriosclerosis.

Frank E. Flowers, Mannington, W. Va.; College of Physicians and Surgeons, Baltimore, 1907; member of the West Virginia State Medical Association; mayor-elect; aged 55; died, March 31, of angina pectoris.

George Henry Lamley ⊕ Blissfield, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901; aged 61; died, March 3, in Toledo, Ohio, of influenza, chronic nephritis and myocarditis.

Lyman George Haskell, Gainesville, Fla.; Boston University School of Medicine, 1897; formerly director of physical education at the University of Florida; aged 67; died, March 18, of a cerebral hemorrhage.

John Frey Binkley, West Palm Beach, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1917; member of the Florida Medical Association; served during the World War; aged 51; died, March 22.

Arthur Le Roy Garrison, Cleveland; Western Reserve University Medical Department, Cleveland, 1902; aged 62; died, March 19, in the Elyria (Ohio) Memorial Hospital of chronic nephritis and uremia.

Frank Washington Tarbell, Smyrna Mills, Maine; Columbia University College of Physicians and Surgeons, New York,

1908; past president of the Aroostook County Medical Society; aged 59; died, February 25.

Edward Stevens Lane, Bristol, Vt.; University of Vermont College of Medicine, Burlington, 1893; member of the Vermont State Medical Society; aged 72; died, March 30, of sclerosis of the coronary artery.

Edgar Dumont Wing, Galesburg, Ill.; University of Pennsylvania Department of Medicine, Philadelphia, 1873; health commissioner; aged 91; died, February 1, of uremia due to prostatic obstruction.

Clifton Dean Briggs, New Bedford, Mass.; Boston University School of Medicine, 1889; at one time physician to the late President Grover Cleveland; aged 72; died, March 21, of coronary thrombosis.

James Lafayette Jordan, Huntsville, Ala.; Birmingham Medical College, 1911; member of the Medical Association of the State of Alabama; aged 47; died, March 21, of hypertension and chronic nephritis.

Alvin Bartley Coxwell, Monroeville, Ala.; Louisville (Ky.) Medical College, 1907; member of the Medical Association of the State of Alabama; aged 55; died, March 23, of coronary thrombosis.

James Warren Rutherford, Chatham, Ont., Canada; University of Toronto Faculty of Medicine, 1899; aged 63; died, February 27, as the result of injuries received in an automobile accident in 1935.

Walter Gilbert Casey ⊕ Talladega, Ala.; University of the South Medical Department, Sewanee, Tenn., 1906; on the staff of the Citizens' Hospital; aged 67; died, March 9, of coronary occlusion.

Levi Harry Leonard ⊕ Manchester, Ohio; Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1895; aged 72; died, March 24, of coronary occlusion.

Rolando Hamilton Henry, Princeton, Ill.; Miami Medical College, Cincinnati, 1884; member of the Illinois State Medical Society; also a pharmacist; aged 82; died, March 25, of coronary thrombosis.

William E. Chapman, Leland, Ill.; Hahnemann Medical College and Hospital, Chicago, 1904; served during the World War; member of the Illinois State Medical Society; aged 63; died, March 19.

John William Barson ⊕ Joplin, Mo.; University of Louisville (Ky.) Medical Department, 1898; on the staffs of the Freeman and St. John's hospitals; aged 76; died, March 15, of heart disease.

Philander A. Wheeler, Lake Wales, Fla.; University of Vermont College of Medicine, Burlington, 1872; aged 91; died, February 18, in the Bartow General Hospital at Bartow of arteriosclerosis.

Joseph B. Trice, Van Buren, Ark. (licensed in Arkansas in 1905); member of the Arkansas Medical Society; formerly a medical missionary; aged 60; died in February at a hospital in Fort Smith.

Martin Hoke, Spring Grove, Pa.; Jefferson Medical College of Philadelphia, 1881; member of the Medical Society of the State of Pennsylvania; aged 79; died, February 21, of mitral stenosis.

Wilbert A. Staley ⊕ Warrensburg, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; aged 67; died, February 9, of coronary sclerosis.

George Howard Pierce, Brooklyn; Yale University School of Medicine, New Haven, Conn., 1886; member of the Medical Society of the State of New York; aged 78; died, February 3, of pneumonia.

Theodore Kynette Gregg, Spartanburg, S. C.; Meharry Medical College, Nashville, Tenn., 1929; aged 37; died, March 28, in St. Agnes Hospital, Raleigh, N. C., of subacute bacterial endocarditis.

Edward Julius Lorenze, New York; University of the City of New York Medical Department, 1886; member of the Medical Society of the State of New York; aged 73; died, February 4.

Leonard Edward Fraser ⊕ Iowa Falls, Iowa; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1905; aged 58; died, February 2, in the Ellsworth Memorial Hospital.

Joseph H. Bertrand, De Forest, Wis.; College of Physicians and Surgeons of Chicago, 1886; member of the State Medical Society of Wisconsin; aged 76; died, March 8, of uremia.

Otto Frederick Jens, Chicago; Jenner Medical College, Chicago, 1901; Illinois Medical College, Chicago, 1902; aged 69; died, March 18, of coronary thrombosis and pernicious anemia.

Benjamin Franklin Jones, Danville, Ky.; Howard University College of Medicine, Washington, D. C., 1890; member of the city council; aged 80; died, March 22, of cerebral hemorrhage.

Harvey Erwin Blacksten, Excelsior, Mo.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; aged 77; died, March 6, in Versailles, of organic heart disease.

Carl Eugene Koenig ⊕ Seattle; Jefferson Medical College of Philadelphia, 1908; member of the Radiological Society of North America; served during the World War; aged 57; died, March 17.

William Halbert McCracken, Alligator, Miss.; University of Tennessee Medical Department, Nashville, 1888; aged 72; died in February at the Baptist Memorial Hospital, Memphis, Tenn.

George William Lawton, Maywood, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; aged 67; died, March 3, in Natchez, Miss., of heart disease.

Jeremiah Thomas Dwyer ⊕ Oswego, N. Y.; Long Island College Hospital, Brooklyn, 1891; on the staff of the Oswego Hospital; aged 68; died, February 27, of coronary artery disease.

Orra M. Flack, Boswell, Ind.; Medical College of Ohio, Cincinnati, 1893; member of the Indiana State Medical Association; aged 72; died, March 11, of an injury received in a fall.

Arthur Robert Lindsay ⊕ Lawrenceville, Ill.; Northwestern University Medical School, Chicago, 1909; aged 53; died, March 15, in a hospital at Vincennes, Ind., of acute cholecystitis.

Charles E. Grayston, Huntington, Ind.; Medical College of Ohio, Cincinnati, 1881; Fort Wayne (Ind.) College of Medicine, 1885; aged 81; died, March 27, of cerebral hemorrhage.

Lawrence Joseph Morton, Brooklyn; Long Island College Hospital, Brooklyn, 1884; for many years on the staff of St. Mary's Hospital; aged 80; died, February 26, of arteriosclerosis.

Harry Theophilus Randle, Aurora, Colo.; Beaumont Hospital Medical College, St. Louis, 1902; aged 66; died, February 17, in Denver of chronic asthma and chronic emphysema.

Emmet Michael Brown ⊕ Beattyville, Ky.; Rush Medical College, Chicago, 1930; county health officer; aged 43; was found dead, March 16, in a hotel at Louisville of myocarditis.

William Posey Blalock, New York; Columbia University College of Physicians and Surgeons, New York, 1937; intern at St. Luke's Hospital; aged 31; died, March 10, of pneumonia.

Marcia Gilmore, Pasadena, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; aged 79; died, February 13, of chronic bronchitis and pneumonia.

Jiles Wade Horn, Grubbs, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1923; served during the World War; aged 50; was found dead, March 20, of heart disease.

Walter Hugh Brent ⊕ Hammond, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1905; aged 60; died, March 18, of heart disease and hypertension.

Cecil Dabney, Baltimore; University of Virginia Department of Medicine, Charlottesville, 1910; at one time a medical missionary; aged 55; died, March 7, of coronary occlusion.

Thomas Wright Collins, Muldrow, Okla.; Medical Department of Tulane University of Louisiana, New Orleans, 1904; aged 70; died, March 13, in a hospital at Fort Smith, Ark.

Lewis Cass Skinner, Knoxville, Tenn.; North Carolina Medical College, Davidson, 1902; aged 72; died, February 8, in the Knoxville General Hospital of chronic myocarditis.

Anna M. Stiles Graves, Newark, N. J.; New York Medical College and Hospital for Women, New York, 1873; aged 86; died, February 20, of a fractured femur received in a fall.

Charles Goldman, Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1901; aged 61; died, January 31, in the Emergency Hospital, Annapolis, Md.

Charles Watts Alexander, Oklahoma City, Okla.; Memphis (Tenn.) Hospital Medical College, 1890; aged 72; died, March 8, of coronary thrombosis and angina pectoris.

Walter B. Braden, Seattle; University of Oregon Medical School, Portland, 1902; aged 66; died, March 7, of coronary thrombosis and cholecystitis with one large gallstone.

W. C. Currey, Flemington, W. Va.; University of Maryland School of Medicine, Baltimore, 1881; aged 85; died, March 25, of chronic myocarditis and arteriosclerosis.

Malcolm Douglas, Santa Barbara, Calif.; Albany (N. Y.) Medical College, 1904; served during the World War; aged 62; died, February 12, of carcinoma of the pancreas.

Robert S. Humphrey, Cherryville, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1874; aged 85; died, February 20, of uremia and chronic nephritis.

Samuel C. Browne, Scio, Ore.; Eclectic Medical Institute, Cincinnati, 1890; aged 83; died, February 28, in the Albany (Ore.) General Hospital of cerebral hemorrhage.

Frederick Russell Tower ✠ Arlington, Mass.; Harvard University Medical School, Boston, 1892; aged 77; died, February 25, in the Ring Sanatorium and Hospital.

Edward Taylor Julian, Harlan, Ind.; Kentucky School of Medicine, Louisville, 1891; aged 73; died, February 25, in St. Joseph's Hospital, Fort Wayne, of uremia.

Herman Bick ✠ New York; University and Bellevue Hospital Medical College, New York, 1915; on the staff of the Fordham Hospital; aged 46; died, January 24.

James Franklin Frye, Whitehouse, Ohio; Western Reserve University School of Medicine, Cleveland, 1929; aged 38; died, March 2, of carcinoma of the stomach and liver.

Carl Eugene Edwards, Bradley, Ohio; Ohio State University College of Medicine, Columbus, 1914; served during the World War; aged 49; died, February 18.

James Tilford Cooley, Waverly, Tenn.; Vanderbilt University School of Medicine, Nashville, 1889; aged 81; died, March 13, of carcinoma of the prostate gland.

Edwin Hungerford, Denver; Eclectic Medical College of the City of New York, 1874; aged 90; died, March 29, of a fractured hip received in a fall and senility.

Alva Melville De Vilbiss, St. Paul, Kan.; College of Physicians and Surgeons, Keokuk, Iowa, 1898; aged 65; died, March 27, of chronic nephritis and uremia.

William Marion Davis, Worthington, Ind.; Marion-Sims College of Medicine, St. Louis, 1899; aged 67; died, March 18, of cerebral hemorrhage and arteriosclerosis.

Samuel Morison McConnell, Rochester, Pa.; University of the City of New York Medical Department, 1879; aged 94; died, February 26, of coronary occlusion.

John Warth English, McDowell, W. Va.; Washington University School of Medicine, Baltimore, 1897; aged 65; died, March 29, in a hospital at Huntington.

Julia B. Day Godfrey, Chicago; Hahnemann Medical College and Hospital, Chicago, 1891; aged 90; died, March 1, of carcinoma of the uterus and vagina.

Finley C. Spates, St. Paul; Hahnemann Medical College and Hospital, Chicago, 1883; aged 83; died, February 26, of hemiplegia and valvular heart disease.

Thomas Jennings Stem, Clovis, N. M.; University of Nashville (Tenn.) Medical Department, 1885; aged 81; died, February 19, of Raynaud's disease.

Thomas W. Burton, Springfield, Ohio; Eclectic College of Physicians and Surgeons, Indianapolis, 1892; aged 78; died, March 23, of interstitial nephritis.

George H. Kriz, Milwaukee; Baltimore University School of Medicine, 1898; aged 65; died, March 6, in the Columbia Hospital of cerebral hemorrhage.

Axel Fritz Grove, Fairfield, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1903; aged 73; died, March 30, of bronchopneumonia.

Joseph J. Kuczkowski, Chicago; Loyola University School of Medicine, Chicago, 1926; aged 42; died, February 23, in Vienna, Germany, of myocarditis.

Frank Warnock Brand, Urbana, Ohio; Homeopathic Hospital College, Cleveland, 1889; aged 72; was found dead in bed, March 29, of heart disease.

Eliza Lawton Whiteley, Lemongrove, Calif.; Hahnemann Medical College and Hospital, Chicago, 1886; aged 85; died, February 19, of arteriosclerosis.

Arche E. Pardue, Hamlin, Texas; Louisville (Ky.) Medical College, 1898; aged 67; died, February 26, of arteriosclerotic heart disease and hypertension.

James Francis Freeman, Evansville, Ind.; University of Birmingham Faculty of Medicine, England, 1875; aged 83; died, March 9, of pneumonia.

Franklin Burton Ladd, Fort Wayne, Ind.; College of Physicians and Surgeons, Keokuk, Iowa, 1888; aged 73; died, March 14, of angina pectoris.

Lottie Ambler Cort, Brooklyn; New York Medical College and Hospital for Women, New York, 1883; aged 79, died, February 14, of hypertension.

Stephen A. D. Miller, Seattle; Starling Medical College, Columbus, 1886; aged 75; died, February 13, of hypostatic pneumonia and Parkinson's disease.

Mathew Samuel Holt, Weston, W. Va.; Jefferson Medical College of Philadelphia, 1877; formerly mayor; aged 88; died, March 31, of pneumonia.

Creed Turner Cannaday, Cotter, Ark.; Memphis (Tenn.) Hospital Medical College, 1898; aged 86; died, February 20, of cerebral hemorrhage.

Henry Barridge Morton, Wichita, Kan.; Marion-Sims College of Medicine, St. Louis, 1895; aged 67; died, February 12, in a local hospital.

William Oliver Brickell, Friendsville, Tenn.; Tennessee Medical College, Knoxville, 1895; aged 70; died, March 27, of coronary occlusion.

Henry Zachariah Ewing, Hartford, Kan.; Kansas City (Mo.) Medical College, 1904; aged 69; died, March 11, of cerebral hemorrhage.

Charles Henry Oakwood, Los Angeles; Medical College of Indiana, Indianapolis, 1883; aged 83; died, February 20, of chronic myocarditis.

Arthur Wegeforth, San Diego, Calif.; Baltimore Medical College, 1890; aged 68; died, February 9, of cardiac decompensation and hepatitis.

William Franklin Howerter, Sciota, Pa.; Medico-Chirurgical College of Philadelphia, 1903; aged 63; died, February 25, of heart disease.

Henry MacVicker Smith, Santa Ana, Calif.; University of Buffalo School of Medicine, 1898; aged 69; died, February 19, of pneumonia.

Henry Blackburn Johnstone, Fenelon Falls, Ont., Canada; University of Toronto Faculty of Medicine, 1907; aged 58; died, February 22.

Francis Coburn Chapin, Cambridge, Mass.; Boston University School of Medicine, 1888; aged 76; died, March 22, of chronic nephritis.

Holdridge L. Henry, Capon Bridge, W. Va.; Baltimore University School of Medicine, 1887; aged 74; died, February 19, of pneumonia.

Eugene Carter Hamley, Glendale, Calif.; Rush Medical College, Chicago, 1902; aged 59; died, February 24, of coronary disease.

G. Walter Barr, Keokuk, Iowa; Jefferson Medical College of Philadelphia, 1884; aged 79; died, March 29, in Spartanburg, S. C.

Joseph Newton Chandler, Weatherford, Texas; Louisville (Ky.) Medical College, 1886; aged 75; died, March 1, of heart disease.

J. Ottis Hart, Benton, Ill.; St. Louis College of Physicians and Surgeons, 1902; aged 60; died, February 25, of myasthenia gravis.

John E. Morton, Spring Valley, Wis.; Milwaukee Medical College, 1897; aged 82; died, February 2, of cerebral hemorrhage.

Clifford B. Colwell ✠ Providence, R. I.; Baltimore Medical College, 1905; aged 57; died, March 9, of cardiorenal vascular disease.

James M. Hindman, Advance, Mo.; St. Louis College of Physicians and Surgeons, 1902; aged 71; died, March 18, of senility.

John James Van Male, Challenge, Calif.; California Medical College, Oakland, 1887; aged 80; died, February 16, of senility.

John H. Judkins ✠ Northfield, Vt.; Baltimore Medical College, 1893; aged 72; died, March 13, of coronary thrombosis.

Alfred G. Ward, Mobile, Ala.; Medical College of Alabama, Mobile, 1894; aged 66; died, February 27, of coronary occlusion.

Thomas McCall Anderson, New York; Baltimore Medical College, 1908; aged 56; died, March 24, of coronary thrombosis.

Sara Eleanore Schwerer, Crafton, Pa.; University of Pittsburgh School of Medicine, 1931; aged 40; died, February 2.

William Grant, Wolfville, N. S., Canada; Halifax Medical College, Halifax, N. S., 1892; aged 78; died, February 5.

H. Frank Clark, Rarden, Ohio (licensed in Ohio in 1896); aged 79; died, March 30, of myocarditis and nephritis.

TREATMENT OF HERPES ZOSTER

To the Editor:—In the March 1931 issue of the *Archives of Dermatology and Syphilology* Dr. E. Wood Ruggles of this state suggested the intravenous injection of sodium iodide as a specific for herpes zoster. In the summer of 1935 I had a succession of twelve or more cases of zoster in a very short time and, recollecting the suggestion of Dr. Ruggles, used the sodium iodide in each case with really miraculous results.

Dr. Ruggles recommended giving 2 Gm. intravenously on the first, second, fourth and seventh days.

The success of this treatment has been so universally satisfactory in my own practice, as well as among the patients of professional brothers whose attention has been called to its efficiency, that I am taking the liberty of urging its exhibition by others who are unfamiliar with its virtue. I note in the latest editions of Sutton and Andrews that this remedy is mentioned but the dosage is not given. In several of my cases in young or delicate women the dose was cut in half. I have also made it a practice of giving the dose selected every other day, and never more than four doses have been found necessary.

NATHAN THOMAS BEERS, M.D., Brooklyn.

SULFANILAMIDE IN EDEMA FLUIDS

To the Editor:—I have not noticed any reports of sulfanilamide concentration in human edema fluid of noninflammatory origin. A patient with intractable pitting edema of the lower extremities due to the nephrotic stage of chronic glomerulonephritis was treated by the insertion of Southey tubes into both legs. Sulfanilamide was given prophylactically to minimize the frequently resultant infection which has brought this often valuable procedure into disrepute. An initial dose of 4 Gm. followed by 1 Gm. every four hours was given, and twenty hours later samples of blood and edema fluid were taken simultaneously. The concentration of sulfanilamide in the two was the same, 4.2 mg. per hundred cubic centimeters.

The diffusibility of the drug into edema fluid is thus even more marked than into the other body transudates. Incidentally, satisfactory drainage was obtained in this case without any inflammatory reaction. It is suggested that taking advantage of the penetration of the drug into edema fluid may render the use of Southey tubes more applicable and less dangerous.

IRVING A. BECK, M.D., New York.
Mount Sinai Hospital.

DETERMINATION OF PROTHROMBIN

To the Editor:—With the rapid development of the subject of vitamin K in the treatment of hemorrhage, a certain amount of confusion can easily occur. Fundamentally all the work on this subject rests on the quantitative determination of prothrombin. Four years ago I described a method for this determination (*J. Biol. Chem.* **109**: lxxiii [May] 1935) and showed that the prothrombin was normal in amount in hemophilia but reduced in a certain number of jaundiced patients. This method subsequently proved itself to be a sensitive test in all known hemorrhagic diseases characterized by a diminution of prothrombin. Because of its simplicity the test has been widely used clinically and, judging from the reports in the literature, has been found quite satisfactory. In a recent paper Drs. Scanlon, Brinkhous, Warner, Smith and Flynn (THE JOURNAL May 13, 1939, p. 1898) call attention to a new bedside test for determining prothrombin which consists in adding 0.9 cc. of blood to 0.1 cc. of thromboplastin. Unfortunately, this test is not new, for I, with Drs. Stanley-Brown and Bancroft (*Am. J. M. Sc.* **190**:510 [Oct.] 1935) used a test almost exactly like theirs (differing only in adding 0.1 cc. of thromboplastin to 1 cc. of blood) for demonstrating a normal prothrombin concentration in hemophilic blood. We did not feel justified at that time in recommending the test as a clinical method. The mechanical difficulties of carrying out a bedside test are well known, especially if it is of a quantitative nature requiring accurate timing with a stop-watch. It seems far preferable to require the little additional work entailed in my method and gain thereby the accuracy which is well justified and demanded, in view of the importance of reliable quantitative data concerning the prothrombin level in jaundiced subjects, newborn babies and other patients potentially in danger of hemorrhage.

ARMAND J. QUICK, M.D., Milwaukee.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TEST FOR ALCOHOL IN URINE

To the Editor:—How are tests to determine the alcoholic content of urine made? What is the technic and interpretation as applied to drunken drivers?

M.D., Wisconsin.

ANSWER.—A simple test for alcohol in body fluids is based on the fact that alcohol can be distilled from an acid mixture and that the color obtained by mixing measured amounts of the distillate with standard potassium dichromate produces changes in color from orange to blue. By preparing test tubes containing known amounts of alcohol and potassium dichromate, permanent color standards can be obtained, which may be used for comparison when performing tests on samples of unknown alcoholic content. The standards may be purchased from the LaMotte Chemical Company, Baltimore, or prepared from the following directions:

Strong Permanent Standards

Color Standards Corresponding to per Cent Alcohol by Weight	Prepared by Using	With Water, Cc.
0.0	.....	1.00
0.05	0.50 cc. of 0.10 per cent alcohol by weight	0.50
0.10	1.00 cc. of 0.10 per cent alcohol by weight	0.0
0.12	0.60 cc. of 0.20 per cent alcohol by weight	0.40
0.14	0.70 cc. of 0.20 per cent alcohol by weight	0.30
0.16	0.80 cc. of 0.20 per cent alcohol by weight	0.20
0.18	0.90 cc. of 0.20 per cent alcohol by weight	0.10
0.20	1.00 cc. of 0.20 per cent alcohol by weight	
0.22	0.73 cc. of 0.30 per cent alcohol by weight	0.27

To each tube add 3 cc. of fifteenth normal potassium dichromate (0.33 per cent in 50 per cent sulfuric acid). Place tubes in boiling water four minutes and seal.

Weak Permanent Standards

Color Standards Corresponding to per Cent Alcohol by Weight	Prepared by Using	With Water, Cc.
0.0	.....	2.0
0.005	1.0 cc. of 0.01 per cent alcohol by weight	1.0
0.010	2.0 cc. of 0.01 per cent alcohol by weight	0.0
0.013	0.52 cc. of 0.05 per cent alcohol by weight	1.48
0.016	0.64 cc. of 0.05 per cent alcohol by weight	1.36
0.019	0.76 cc. of 0.05 per cent alcohol by weight	1.24
0.022	0.88 cc. of 0.05 per cent alcohol by weight	1.12
0.025	1.00 cc. of 0.05 per cent alcohol by weight	1.00
0.028	1.12 cc. of 0.05 per cent alcohol by weight	0.88
0.031	1.24 cc. of 0.05 per cent alcohol by weight	0.76
0.034	1.36 cc. of 0.05 per cent alcohol by weight	0.64
0.037	1.48 cc. of 0.05 per cent alcohol by weight	0.52

Add 1 cc. of potassium dichromate reagent to each tube. Place tubes in boiling water bath twelve minutes.

Technic of Test: Distil a mixture of 10 cc. of urine with about 10 cc. of half saturated picric acid containing about 10 per cent tartaric acid, collecting the first 10 cc. of the distillate and mix. In separate tubes similar to those used for the standards, place 1 cc. in one and smaller measured

amounts in the others, making the volume up to 1 cc. in each case. Add 3 cc. of the potassium dichromate reagent to each tube and place in boiling water bath four minutes. Compare colors with those of the standard scale. Divide the reading by the fraction of a cubic centimeter of distillate used, which gives the percentage of alcohol by weight. The use of several tubes permits close checking of the results and gives greater opportunity for having readings on the scale.

If results are too low to be read, use the weak standards, with 2 cc. of the distillate and known smaller amounts, bringing the volume to 2 cc. in each case, add 1 cc. of the reagent to each tube and place tubes in boiling water twelve minutes.

If blood is being tested take 2 cc. of whole blood, plasma or serum, add about 15 cc. of the picric-tartaric reagent and collect the first 10 cc. of the distillate. This is tested on the weak standard scale and the result multiplied by 5. Specimens of urine which have been saturated with benzoic acid retain their alcoholic content indefinitely.

Interpretation: No minimal figure of alcoholic content in body fluids can be set as having absolutely no effect on individuals. However, most persons are definitely under the influence of alcohol at 0.10 per cent, and all who have been examined under well controlled experimental conditions are found to have lost some of that clearness of intellect and control of themselves which they would normally possess, when the alcohol reaches 0.20 per cent. The Committee on Tests for Intoxication of the National Safety Council, therefore, recommends that persons with a concentration of alcohol of less than 0.05 per cent in the blood or 0.07 per cent in the urine should not be prosecuted as being under the influence of alcoholic liquor. When the alcoholic reading is between 0.05 per cent in the blood (or 0.07 per cent in the urine) and 0.15 per cent in the blood (or 0.20 per cent in the urine) the alcohol test can be used for confirming obvious intoxication. When the alcoholic concentration exceeds 0.15 per cent in the blood or 0.20 per cent in the urine there is sufficient impairment to diagnose the person as being under the influence of alcohol even without confirmation by physical signs. These figures are needlessly high but have been accepted as practical since there will be no danger of injustice. An additional important interpretation of the results is the possibility of calculating the amount of unoxidized alcohol in the body at the time the specimen was taken. For example, a person weighing 150 pounds whose urine contains 0.20 per cent of alcohol has accumulated in his body 4 ounces (120 cc.) of absolute alcohol by volume.

TRANSVERSE MYELITIS AND NEOARSPHENAMINE

To the Editor:—A 50 year old woman with asymptomatic syphilis was given a fifteen weeks course of bismuth followed by two injections of neoarsphenamine (0.3 and 0.45 Gm.). After the second injection of neoarsphenamine there was nausea and vomiting, a maculopapular eruption, edema of the face and (three days after the injection) sudden paralysis of the legs and bladder. The spinal fluid gave a negative Wassermann reaction, an 0—0 colloidal gold curve and 5 cells. Despite repeated doses of 1 Gm. of sodium thiosulfate intravenously, the use of large doses of thiamin chloride and whole B complex, the patient at present, ten days after the onset of the paralysis, shows no change. The cranial nerves are normal, as are the upper extremities. There is a band of hyperesthesia at the level of the umbilicus (the tenth thoracic vertebra). From the hips down, including the saddle area, there are absence of pain and temperature sensation, normal sense of position, movement and vibration, and absolute paralysis. The abdominal reflexes are absent. The knee jerks and ankle jerks, at first diminished, are now hyperactive and equal. There is a bilateral Babinski reflex. Plantar stimulation frequently results in a primitive withdrawal response of the extremity. Besides catheterization and antiseptic treatment to the bladder, the patient is receiving increasing doses of potassium iodide and moderate doses of vitamin B complex. What additional therapy can you suggest and what is the prognosis? Do you believe that this patient had vascular thrombosis, hemorrhage or myelitis in the thoracic cord?

M.D., Indiana.

ANSWER.—From the description and history, it would appear that a transverse myelitis had developed in this patient. The treatment is symptomatic; namely, care of the bladder, massage of the lower extremities, and local heat in the region of the thoracic vertebra, now that sodium thiosulfate has been given. The prognosis is indeterminate, since about 30 per cent of these patients regain function of the lower extremities, undoubtedly depending on the amount of hemorrhage that has occurred in the spinal cord. This complication occurs often in patients who have an intercurrent respiratory infection and is also seen in persons who have not had arsphenamine, so it is not possible to incriminate only the arsenic in those cases in which such treatment has been given. The fact that this patient was demonstrating evidence of intolerance to the neoarsphenamine, however, lends weight to the inference that the arsenic in this case assumed an etiologic role.

ANGIONEUROTIC EDEMA FROM FRYING BEEFSTEAK AND FROM OXYDOL SOAP

To the Editor:—Six months ago a white woman aged 32 began to have infrequent mild attacks of angioneurotic edema when she fried beefsteak or used oxydol soap. The attack is not brought on by using the same shortening for frying other foods or in the use of other soaps nor is it brought on with the ingestion of beef. What tests can be made, and can the patient be desensitized? The attacks are now much more frequent and severe. There is no history of familial allergy. If she cannot be desensitized, what is the best form of treatment for prevention?

M.D., Michigan.

ANSWER.—Instances of allergic reactions, both of the respiratory and of the cutaneous type, due to odors from the frying or cooking of foods are not uncommon. In the majority of such cases of food sensitivity ingestion will also cause allergic symptoms. However, there are undoubted instances in which allergens will cause allergic manifestations only by inhalation and not by ingestion. Examples of these are bakers who are sensitive to wheat flour and can eat wheat products without any disturbance. During the ordinary process of cooking beef, no doubt the major part of the allergic activity of this food is destroyed, and what is left undestroyed may be so thoroughly digested that but little of the active element goes into the circulation. Oxydol soap, as is the rule with many soaps of similar character, has no doubt as its basis beef fat. This may account for the similarity in action between the soap and the frying of beefsteak. However, this soap also has a fairly strong chemical irritant which may act in a nonspecific way to disturb the allergic individual. The test that would appear to be indicated here is a test with beef protein. If the latter reacts, desensitization treatment with a beef extract might result in a sufficiently great tolerance to prevent symptoms. If the patient cannot be desensitized, it is likely that the preparation of beefsteak by such methods as broiling will eliminate the difficulty.

COCCYGODYNIA

To the Editor:—Would you kindly outline the treatment for coccygodynia? In a case in which presacral nerve resection is indicated for other conditions would the coccygodynia be relieved?

M.D., California.

ANSWER.—Coccygodynia usually responds to conservative measures: rest, avoidance of pressure on the coccyx, warm baths and sometimes radiant heat. If this fails, removal of the coccyx gives relief in the majority of cases.

A generation ago the indiscriminate use of coccygectomy tended to discredit the operation, but in recent years there has been a more careful selection of cases, limiting the selection to those cases wherein the pain is confined to the coccyx only. Many times neurasthenic persons complain of radiating pains up the spine in the region of the sacro-iliac joints, and the pain in the coccyx is only one of many complaints. These patients do not respond well to coccygectomy.

It is doubtful whether resection of the presacral nerve would relieve pain in the coccyx.

ACCURACY OF BLOOD CULTURES IN BACTEREMIA

To the Editor:—In infections of the blood stream such as streptococcic septicemia, are groups of the pathogenic organism always present in the circulating blood or are these organisms present only at infrequent intervals? In other words, is there not a great possibility of many positive blood cultures reported by laboratories being contaminations rather than micro-organisms from the blood streams, as suggested by Boyd in his Surgical Pathology?

M.D., Kentucky.

ANSWER.—In infections of the blood stream such as streptococcic septicemia, organisms may be constantly present in the blood stream or these organisms may be present only at intervals. A distinction is sometimes made, more or less theoretically, between septicemia, in which bacteria supposedly multiply in the blood stream, and bacteremia, in which organisms are in the blood stream at intervals but are destroyed at a rate somewhat the same as their rate of entry. This would have no bearing, however, on the question as to whether or not any positive blood cultures reported by laboratories are contaminations rather than micro-organisms from the blood stream. This question may be decided by the nature of the organism in question. For instance, it is more likely that Bacillus subtilis would be a contamination than an actual invader of the blood stream. With a staphylococcus it might come either from the skin as a contamination or from the blood stream itself. Whether it is one or the other might be decided by plate cultures better than by liquid cultures, because in case the organism came from the blood it would be present in larger numbers in the plates. On the other hand, when such organisms as typhoid bacilli are found in blood cultures the chance of their being a contamination is remote. In any case, the care in technic is a factor in such decisions.

CHRONIC ARTHRITIS AND DIPHTHERIA

To the Editor:—Two cases of chronic arthritis which developed after diphtheria raise the question as to whether or not diphtheria may be the causative factor of a chronic type of arthritis. (I am aware that infectious diseases frequently cause acute arthritis.) Have you any information relative to such a probable infection and can you suggest any therapy that might be helpful in postdiphtheritic arthritis? M.D., New York.

ANSWER.—No reference has been found to chronic arthritis of diphtheritic origin. According to Hench (Nelson Loose-Leaf Surgery, 1938) the joints may occasionally become swollen and painful early in the course of diphtheria, and in such instances specific organisms have been isolated. No details are given as to the duration of the arthritis in these cases. In one large series of cases of chronic arthritis (Bannatyne, 1898) there was a report of two patients who dated the onset to an attack of diphtheria, but again no details are given. Since attacks of rheumatoid arthritis often follow infections of varying types, only a coincidental or precipitating role can be assigned to diphtheria in these two cases without further evidence. We are unable to suggest any specific therapy for the inquirer's cases but would advise culture of joint fluid, if obtainable, and even synovial biopsy in order to establish a diagnosis.

NO KNOWN NARCOTIC ACTION FROM ELEPHANT TREE

To the Editor:—1. Along with a number of other amateur naturalists, I have lately been much interested in the finding of a half dozen or so specimens of the rare elephant tree in southern California. It grows in inaccessible places in the mountains of the desert and botanically is Bursera microphylla. I am one of the few white people who have seen it, and in tracing out all the information that I could get about it I came on some tales of the Cahuilla Indians—now living near the famous resort at Palm Springs—to the effect that the tree, or some part of it, has poisonous or narcotic effects. These tales are vague, for the old Indians are too superstitious and afraid of the tree to tell much about it and the younger ones do not know. I could not discover the part of the tree used by them nor the mode of preparation, but it seems certain that they used it for its physical effects; from the description, I was reminded of marihuana and the cannabis drugs. Can you give me any proved facts about it? What poison or narcotic is in it, what part of the tree contains it, what are the pharmacologic effects? 2. Can you tell me what poisons were used in the "poison rings" used in Roman times for suicide and during the Renaissance for murder? There are not so many poisons violent enough to kill in the dose that could be concealed in a ring, and in days when the drugs were not so highly purified a lethal dose must have been even more bulky. Doubtless many tales of them are much exaggerated, but there seems to be no doubt of the actual use of some such device, and I should be interested to know what drugs were actually used. M. J. GROESBECK, M.D., Porterville, Calif.

ANSWER.—1. No references could be found in the accessible literature to Bursera microphylla, but quite a number of other species have been studied. These all contain aromatic resins and have been used as vulnerary, alterative, antispasmodic, antirheumatic and similar indefinite indications, like elemi, aloe wood or guaiac. Nothing is known about narcotic actions, but odorous resins are frequently used in religious ceremonials. "Incense" is a well known example.

2. There is no definite information about poison rings. One guess is as good as another, and the best guess perhaps is that mystery is often thickest when there is nothing to hide.

CHRONIC MICROCOCCUS CATARRHALIS PROSTATITIS

To the Editor:—A white man aged 26 has been treated for several months for a chronic prostatitis. He has no subjective symptoms, but the prostate is tender on palpation. The causative organism by culture and by fermentation reactions was found to be Micrococcus catarrhalis. His wife was first seen by me because of a severe cervicitis, which proved to be due to the same organism. Several years ago a similar cervicitis developed in a woman following intercourse with this man. Treatment has consisted of prostatic massage at weekly intervals and a course of neoarsphenamine 0.3 Gm. at weekly intervals. Sulfanilamide 80 grains (5.3 Gm.) was given but, because of nausea and the patient's inability to work, it was discontinued after two days. Since then he has continued the prostatic massages at weekly intervals and is taking methenamine and ammonium chloride 45 grains (3 Gms.) each for five days, alternating with citrocarbonate for five days. The literature seems to be void of suggestions on the treatment of Micrococcus catarrhalis prostatitis. The patient has chronic infected tonsils and I wonder whether this could be the source of the prostatitis. I would appreciate any further suggestions as to treatment. PAUL W. TULLY, M.D., Temple City, Calif.

ANSWER.—Chronic prostatitis is an extremely resistant condition to treat. With the apparent long duration of treatment in this case, urethroscopic examination to rule out the presence of dilated ducts should be performed. If prostatic calculi have not been excluded by x-ray examination of the prostatic area, this should be done. In view of the finding of Micrococcus catarrhalis, a thorough search for dental and tonsillar foci is advised, with eradication if present. After this has been done, prostatic massages might be continued at intervals of every three to four days, along with one of the newer derivatives of sulfanilamide which might be more easily tolerated. Vesical irrigations and posterior urethral instillations with a suitable antiseptic are often of value in treating this condition.

TESTS FOR GAS POISONING

To the Editor:—Can you refer me to any tests which would be significant in connection with gas poisoning? Our gas here is a mixture of natural gas and that derived from coke. The situation is one in which a child suffered a moderate degree of gas poisoning.

FRED MOORE, M.D., Des Moines, Iowa.

ANSWER.—Natural gas is unlikely to contain dangerous quantities of carbon monoxide, but artificial fuel gas may be rich in carbon monoxide content. At the time of the alleged gassing of the child it would have been possible to determine the extent of the hemoglobin fixation by carbon monoxide. Several tests of this character are available, including the Christman test (Christman, A. A., and Randall, E. L.: A Convenient and Accurate Method for the Determination and Detection of Carbon Monoxide in Blood, *J. Biol. Chem.* **102**:595 [Oct.] 1933), which is one of the best, and the pyrotannic method, which is carried out more readily, is more frequently available but is less accurate than the Christman test. The making of examinations of the patient at this late time is of little avail. The quantity of carbon monoxide in the gas supply is undoubtedly known to the purveyor and, in addition, may be determined by any good testing laboratory.

ZEOLITE WATER SOFTENER

To the Editor:—A patient who suffers from ureteral stones has been advised to drink soft water, as the water here is rather heavy with salts. He has brought in to me a water softener put out by the National Aluminate Company, Zeolite Department, 6216 West Sixty-Sixth Place, Chicago. Can you give me any information about this product and is the water passed through it fit for drinking purposes? I will appreciate your advice on this matter at your earliest convenience.

J. E. GARDNER, M.D., Portales, N. M.

ANSWER.—The type of water softener mentioned, if operated properly, should give a soft water. The effect of softening water by the zeolite process is to exchange calcium and magnesium in the dissolved salts of the water for sodium, which is contained in the zeolite, the result being to reduce the hardness in the water treated. The water after being softened will, however, contain dissolved salts. A practical way to eliminate all dissolved salts in water used in small quantities for medicinal purposes would be to use distilled water.

NIGHT CHILLS AND LOW BLOOD PRESSURE

To the Editor:—A man aged 56 has severe chills at night. He has to get up and walk around the house to obtain relief. He sometimes becomes rigid and afterward sweats. This has been going on for several years. He has no ambition. The attacks affect the pit of the stomach and he has a disagreeable feeling in the bowels at that time. He is thin and active, being the baggage master at a railroad station. He does heavy lifting. The appetite is good and the bowels are regular; he appears nervous, can't keep his hands still, has been sleeping pretty well until lately and perspires easily. The heart is normal, with a pulse rate of 80, somewhat weak; the blood pressure is 80 systolic 60 diastolic. I have given him all kinds of medicine to raise the blood pressure, diathermy up and down the spine plus massage of the spine. Nothing will raise the blood pressure. He is active and seems normal except for the chills and the low blood pressure. Can you tell me what ails him and what the treatment is?

M.D., New Hampshire.

ANSWER.—Many important details that might contribute toward a diagnosis are omitted from this question. Are these real chills or are they chilly sensations? Real chills are always accompanied by and followed by a rise in temperature and are usually indicative of infection, either parasitic or bacterial. Is the rigidity a convulsive seizure or merely stiffness of the muscles? Accurate observation in these points would do much to limit the possibilities.

On the basis of the information given, this appears most likely to be a case of autonomic instability. It seems unlikely that there is parasitic or infectious disease, although parasitic diseases such as malaria or filariasis sometimes continue intermittently over a period of years.

Addison's disease or adrenal insufficiency must be considered. Is there pigmentation of the skin or has a blood chloride determination been done? Marked anemia, either secondary or primary, might produce such a picture.

A low blood pressure per se is not particularly objectionable, but a systolic pressure of 80 mm. is always a source of anxiety.

The correspondent does not state what medication has been used apart from diathermy and massage. Symptomatically, amphetamine sulfate might be helpful, but it may produce wakefulness if given too late in the day. Adrenal cortex extract and sodium chloride should be beneficial if this is adrenal insufficiency. A more accurate diagnosis would assist in planning the therapy.

NOCTURNAL PAINFUL URINATION IN INFANT

To the Editor:—A boy aged 11 months has been waking out of a sound sleep and crying severely. The crying continues until he urinates, after which he quiets down and goes to sleep. I have seen him once in such an attack, which lasted about a half hour; he seemed unable to urinate although he tried frequently. At this time there seemed to be tenderness over the region of the bladder and palpation there would increase the severity of his crying. I finally put him in a hot sitz bath, with relief in a few minutes. The frequency of the attacks is variable, sometimes coming on several nights in succession and then going for a week or two before another attack. The day after an attack there is usually a pronounced diuresis. Urinalysis has been consistently negative with specimens taken immediately after the attack, the next morning and at intervals between attacks. The attacks do not seem to be increasing in frequency. I put him on atropine sulfate 1: 1,000, of which he is getting three drops three times a day, with apparent relief. Other than a spasm of the bladder and sphincters, could you give any suggestions as to this case?

M.D., Minnesota.

ANSWER.—Congenital valves are a form of anomaly causing intermittent obstruction of the posterior urethra. They are composed of one or two membranous folds with one end attached to the verumontanum and the other end to the lateral urethral wall. As urine flows from the bladder the folds are ballooned out, causing a diminution of the urethral lumen and hence obstruction. An iris diaphragm, a thin membranous congenital band completely or partially encircling the posterior urethra, can also cause partial obstruction. Posterior urethral obstructions are being described with increasing frequency in young children. They are rarely encountered in girls. They usually become manifest during the first year of life.

Obstruction of the bladder neck also seems to occur as a congenital anomaly as a shelf or bar on the floor of the bladder neck. This is also mostly in males, but symptoms usually appear after 1 year of age.

A bladder stone with intermittent obstruction must also be considered, although it is doubtful whether the urine would remain repeatedly negative.

An ulcerated meatus of the penis from ammoniacal urine might temporarily adhere (fibrin and the like) until the pressure of the urine behind forces the meatal lips open. This could be detected by inspecting the end of the penis.

The other conditions mentioned would require urologic investigation.

COMMUNION CUP AND BACTERIA

To the Editor:—*Has there been any bacteriologic investigation regarding* the common communion cup as used in the Episcopal Churches? I have never heard of any such researches being made, but the practice of *passing the cup from lip to lip certainly stirs the imagination of any* one with a medical training. Whenever I mention the subject, church officials reply "Did you ever hear of an infection from this source?" This unscientific answer does not satisfy me. I still believe that bugs can get by a church door, and that even the most devout may be a host to a Tubercle bacillus—even a spirochete!

W. H. GODFREY, M.D., Toronto, Canada.

ANSWER.—No published report on the survival of bacteria on the chalice used in the Episcopal Church has been found. The possibility of the transmission of infection by this means is not to be *denied, but ancillary evidence suggests that it is* unlikely. The bactericidal activity of some of the heavy metals, or "oligodynamic action of metals," is well known. Copper, silver and gold coins, for example, carry few bacteria and rarely, if ever, function as fomites in the transmission of disease. Furthermore, the bactericidal activity of silver has been utilized, by the German workers in particular, in the disinfection of water by the catadyne process and by filtration through the so-called silbersand filters. The rim of the silver chalice, therefore, unlike that of the drinking glass or china cup, is not an indifferent surface on which the survival time of a microorganism is conditioned by its resistance to drying but is in itself actively bactericidal. After one person has made his communion, the officiating priest wipes the rim of the chalice and rotates it slightly so that the next person puts his lips to an adjoining spot. Commonly from three to five minutes elapses before a particular section of the chalice rim is touched to the lips of a second person. Bacteria that are present are therefore exposed in a thin film of mixed saliva and wine to the polished silver surface for this length of time before they are transferred to the lips of another person. The bactericidal activity of the alcohol present in the wine, even in the fortified wines such as port, is probably negligible. On the other hand, wine in prolonged contact with the chalice may acquire some degree of bactericidal activity, and its dilution with water containing appreciable quantities of residual chlorine may add to its slight germicidal properties. The fact that no epidemic has been traced to the use of the silver chalice is in itself of no little significance and is suggestive of the relative unimportance of the common use of the chalice in the transmission of disease.

ALLERGY TO LIVER PREPARATIONS

To the Editor:—A patient with pernicious anemia is markedly sensitive, allergically, to liver extract. Up to the present time I have tried Lilly's liver extract and the concentrated so-called reticulogen, and a liver extract put out by the U. S. Standard Products Company. About twenty minutes after each injection severe asthma and shock develop. She is, however, able to take liver extract by mouth without developing any allergic reactions, but I have been unable to give her sufficient liver extract to keep up her blood count. Are there any other suggestions as to forms of liver extract that I might use? Would ventriculin used alone be sufficient?

C. G. OCHSNER, M.D., Wabasha, Minn.

ANSWER.—This is a difficult situation. Liver extract from another manufacturer might be tried, preferably a highly refined and concentrated extract. In most cases of this kind, however, the patient is sensitive to all parenteral liver extracts and oral treatment must be used exclusively. Ventriculin alone or oral liver extract alone is usually satisfactory. Perhaps the dose used in this case was not large enough. In some instances spontaneous disappearance of the allergic condition has been noted after a period of months on oral treatment.

STERILIZATION OF PESSARIES

To the Editor:—Can you tell me the best method of *refinishing, sterilizing* and keeping hard rubber pessaries in condition for use? Up to the present I have been keeping them in solution of formaldehyde, but I find that the pessary loses its smooth finish in this solution.

THADDEUS L. MONTGOMERY, M.D., Philadelphia.

ANSWER.—*All pessaries, whether newly purchased or removed* from the vagina of a woman to be used again, should be thoroughly washed with soap and water and soaked in alcohol for a few days. They should then be placed in a sterile container and kept in it until ready to be used. A smooth finish is not essential for the proper functioning of a pessary.

DIET FOR ADDISON'S DISEASE

To the Editor:—With regard to a varied diet for Addison's disease I *have referred to my back numbers of medical journals and have obtained* some valuable information, but the diet suggested in them is quite confining. I would appreciate knowing where I might obtain one which has many more possibilities of a varied bill-of-fare.

R. F. DEARBORN, M.D., Orangeville, Ill.

ANSWER.—Investigations indicate that considerable advantage attends the restriction of potassium in the diets of patients with Addison's disease. To effect this without interfering with the palatability of the diet requires careful planning. Detailed directions for arranging such a diet have been published by Sister Mary Victor of the Department of Nutrition, St. Mary's Hospital, Rochester, Minn. (*J. Am. Dietet. A.*, December 1938). Reprints of the article can be obtained from the author.

INTESTINAL IMPLANTATION OF ACIDOPHILUS BACILLUS

To the Editor:—Please be good enough to outline the best system for implanting the acidophilus bacillus in the intestine. Can this be accomplished satisfactorily without the use of intestinal irrigations? If intes*tinal irrigations should be employed,* would it be satisfactory to have the patient drink 1 quart (1 liter) of isotonic salt solution the first thing in the morning once or twice a week as a substitute for intestinal irrigation?

M.D., New York.

ANSWER.—Acidophilus bacilli may be implanted in the intestine in two ways: They may be given in the form of acidophilus buttermilk or of acidophilus bacilli prepared in some other viable form. The preparation should be taken at least one hour before mealtime. Liquids leave the stomach sooner and the bactericidal action of the gastric juice does not have time to attenuate the organism. Also a glassful of buttermilk may be taken at bedtime.

This growth in the intestine is markedly accelerated if the patient consumes at least 25 to 50 Gm. of lactose a day. If one wants to implant the organism locally into the intestine the

best method is to give an enema with physiologic solution of sodium chloride and after that 1 ounce (30 cc.) of a good viable broth culture, injected by rectal tube with the patient lying on the left side, and then rolling over on the back and then over on to the right side. This should be repeated daily for two weeks, and the cultures may be kept up by mouth for an indefinite time.

If one employs a more vigorous intestinal irrigation this material can be injected at the end of the completion of the irrigation. Finally, patients should be instructed during this time to be on a relatively low protein, high carbohydrate diet.

ELECTRICAL STIMULATION OF BRAIN

To the Editor:—Does psychiatric literature report electrical shock procedures for the treatment of mental disorders? Would it be possible to produce epileptiform attacks by stimulation of the motor area of the brain? Could this area be isolated and stimulated through the skin? Should alternating or continuous current be used and in what strength and in what arrangement? What would be the dangers, contraindications and possible death limit? ERNST FANTL, M.D., Beacon, N. Y.

ANSWER.—There is no electrical shock procedure for mental disturbances. Epileptic attacks can be produced by stimulating the motor area of the brain, but only when the brain is exposed; this is done only for localizing purposes at the time of operation. With the skull intact, this cannot be done with any degree of safety.

NO METHOD TO REDUCE SKIN PIGMENT OF NEGROES

To the Editor:—Has an attempt ever been made to change the color of the skin of Negroes to white, at least the face and hands? What chemicals would have the quality to destroy the melanin without harming the rest of the skin? Could a white skin color be given temporarily or permanently to Negroes? E. FANTL, M.D., Beacon, N. Y.

ANSWER.—There is no known practical method to reduce the quantity of pigment in Negro skin so that the appearance of the skin of a Caucasian is approached. There may be a loss of pigment from patches of the skin in Negroes just as in persons of other races in vitiligo. Rarely this loss may be general. The color of the skin in such instances becomes a dead white. Even blond persons are somewhat pigmented, which gives them a different hue from that seen in vitiligo.

TWINS AND STERILITY

To the Editor:—Is the percentage of sterility greater among twins and if so is it greater among enzygotic or dizygotic twins? M.D., Illinois.

ANSWER.—There is no evidence indicating that human twins are any more or less sterile than singly born persons. The idea about sterility in twins comes from the freemartin situation in cattle. There is no such situation in human beings.

GENITO-ANAL PRURITUS

To the Editor:—About four weeks ago a man aged 34, an office worker, complained of pruritus ani of five days' duration. The anus appeared mildly inflamed, edematous and slightly prolapsed. A tentative diagnosis of beginning hemorrhoids was mentally made. The patient was given suppositories. One week later the pruritus had spread to the scrotum and five days later to the shaft of the penis. The itching was intense. The lesion could be observed on the scrotum and penis. It consisted of a reddened glazed appearance of the skin with slightly elevated, irregularly shaped pinpoint papules. Relief could not be obtained from ammoniated mercury and even ointment of nupercaine liberally applied failed to give the patient comfort. A bath (sitz) in sodium bicarbonate solution caused only smarting and gave no relief. During the past three weeks the itching has awakened the patient three or four times a night. A week ago the pruritus in the anus subsided, as did the itching of the scrotum, and four days ago the itching disappeared from the penis. Two days ago the symptoms recurred in the anus and yesterday all the symptoms returned and there is now itching of the anus, the scrotum, the penis and the groins. Any advice as to diagnosis and treatment will be appreciated. M.D., Pennsylvania.

ANSWER.—From the description given of the original appearance of this patient's anal area it seems reasonable to assume that the condition was an inflammatory response to a local irritant. This may have been of external origin or possibly from the gastrointestinal tract. Infection would be less likely, according to the description. It is entirely possible that continued exposure to an irritant or the treatment may have caused the extension of the dermatitis to the genitalia. Sudden recurrence of the condition supports the probability of an irritant as the cause of the condition, and further extension to the groins might be expected.

Treatment at this stage should consist of the mildest soothing agents available. Hot compresses of boric acid solution for from fifteen to twenty minutes several times a day, with interim application of calamine lotion N. F., plus 0.5 per cent phenol, should afford relief from pruritus and allay inflammation. When the areas become dry, a bland ointment such as zinc oxide ointment or boric acid ointment may be applied.

Meanwhile a painstaking search should be instituted for any possible sources of irritation, including home contacts, hobbies, recreational habits, excursions into the country, self medication for real or fancied anorectal troubles, laxatives or other oral medication, dietary habits, toilet tissues, soaps or other cleansing agents, laundry, clothing and the like.

When the condition has subsided, or sooner if feasible, the possibility of infection may be ruled out by microscopic or cultural investigation.

Council on Medical Education and Hospitals

ADDITIONAL HOSPITALS APPROVED

The Council on Medical Education and Hospitals of the American Medical Association has given its approval to the following hospitals since the publication of the last previous list in THE JOURNAL, March 11, 1939:

Hospitals Approved for Intern Training

St. Joseph Infirmary, Atlanta, Ga.
Moline Public Hospital, Moline, Ill.
Edward W. Sparrow Hospital, Lansing, Mich.
St. Lawrence Hospital, Lansing, Mich.

Residencies and Fellowships

Leo N. Levi Memorial Hospital, Hot Springs National Park, Ark.
Mixed.
Baptist State Hospital, Little Rock, Ark.
Medicine, Surgery.
Collis P. and Howard Huntington Memorial Hospital, Pasadena, Calif
Medicine.
Denver General Hospital, Denver.
Fractures.
Georgetown University Hospital, Washington, D. C.
Dermatology-Syphilology.
Providence Hospital, Washington, D. C.
Surgery.
Sibley Memorial Hospital, Washington, D. C.
Obstetrics.
Tuberculosis Sanatorium (Glenn Dale, Md., P. O.), Washington, D. C
Tuberculosis.
St. Joseph Infirmary, Atlanta, Ga.
Medicine, Surgery.
Children's Memorial Hospital, Chicago.
Orthopedics.
Grant Hospital, Chicago.
Obstetrics, Surgery.
Mercy Hospital-Loyola University Clinics, Chicago.
Medicine, Obstetrics-Gynecology, Surgery.
Mount Sinai Hospital, Chicago.
Medicine.
Research and Educational Hospital, Chicago.
Anesthesia.
University of Chicago Clinics, Chicago.
Tuberculosis.
Kosair Crippled Children Hospital, Louisville, Ky.
Orthopedics.
Sydenham Hospital, Baltimore.
Communicable Diseases.
Union Memorial Hospital, Baltimore.
Obstetrics.
Massachusetts Memorial Hospitals, Boston.
Urology.
Mary Imogene Bassett Hospital, Cooperstown, N. Y.
Medicine, Surgery.
Charles S. Wilson Memorial Hospital, Johnson City, N. Y.
Pediatrics.
French Hospital, New York City.
Anesthesia, Obstetrics.
New York Polyclinic Medical School and Hospital, New York City.
Gynecology, Medicine.
Watts Hospital, Durham, N. C.
Pediatrics, Urology.
University of Oregon Medical School Hospitals and Clinics, Portland.
Anesthesia, Urology.
Harrisburg State Hospital, Harrisburg, Pa.
Psychiatry.
Friends Hospital, Philadelphia.
Psychiatry.
Temple University Hospital, Philadelphia.
Pediatrics.
Woman's Hospital, Philadelphia.
Gynecology, Medicine, Obstetrics, Surgery.
Medical Arts Hospital, Dallas, Texas.
Mixed.
Mary Fletcher Hospital, Burlington, Vt.
Medicine.
Charleston General Hospital, Charleston, W. Va.
Traumatic Surgery.
St. Francis Hospital, Charleston, W. Va.
Mixed.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, June 10, page 2461.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, June 19-21 and Sept. 11-13. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. *Written.* Various places throughout the United States, Sept. 9. Applications must be filed by July 11. *Oral.* Part II. Philadelphia, Oct. 14-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Philadelphia, Oct. 30-Nov. 1. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Various sections of the United States, Oct. 16 and Feb. 19. Formal application must be received before Aug. 20 for the Oct. examination and on or before Jan. 1 for the Feb. examination. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Part I (Group B)* will be held in various cities, Dec. 2. *Part II (Groups A and B)* will be given at Atlantic City, N. J., June 6-8. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: *Written.* August 5 and April 6. Formal application must be received before July 1 for the August examination and before January 1 for the April examination. *Oral.* Chicago, Oct. 7 and New York, June 10. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Boston, January. *Applications must be filed on or before Nov. 1.* Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Memphis, Nov. 22-23. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: Cincinnati, Nov. 15. Appointments must be made before July 15. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, December. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

Arizona January Report

Dr. J. H. Patterson, secretary, Arizona State Board of Medical Examiners, reports the written examination held at Phoenix, Jan. 4-5, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Four candidates were examined, all of whom passed. One physician was licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Southern California School of Medicine		(1935)	88.4
Chicago Medical School		(1938)	80.4
Rush Medical College		(1936)	87.3
Columbia Univ. College of Physicians and Surgeons		(1930)	85.6

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Nebraska College of Medicine		(1932)	Nebraska

Illinois January Examinations

Mr. Homer J. Byrd, superintendent of registration, Department of Registration and Education, reports the written examination (graduates of foreign schools given also a practical test) held in Chicago, Jan. 24-26, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Seventy-two candidates were examined, sixty-eight of whom passed and four failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Howard University College of Medicine		(1937)	82
Chicago Medical School		(1939)	81*
Loyola University School of Medicine		(1939)	80, 82
Northwestern University Medical School		(1937) (1938)	87, 79, 82, 82, 82, 83, 83, 83, 84, 84, 84, 84, 85, 87, 87, 87*
Rush Medical College		(1936) (1937)	82,* 81, 82, 83, 85, 85, 86, 88
School of Med. of the Division of Biological Sciences		(1937)	86
University of Illinois College of Medicine		(1936) (1937)	78, 87, (1938) 80, 81, 81,* 82, 82, 83, 83,* 84, 84, 85, 85, 85,* 87,* 87, 88
University of Buffalo School of Medicine		(1936)	80
University of Rochester School of Medicine		(1937)	84
University of Wisconsin Medical School		(1935)	76*
University of Toronto Faculty of Medicine		(1937)	82
University of Western Ontario Medical School		(1935)	83
McGill University Faculty of Medicine		(1937)	82, 83
Medizinische Fakultät der Universität Wien		(1925) 76, (1929)	78
Université de Liège Faculté de Médecine		(1934)	79
Deutsche Universität Medizinische Fakultät, Prag		(1929)	81
Université de Nancy Faculté de Médecine		(1936)	75
Université de Paris Faculté de Médecine		(1937)	79
Christian-Albrechts-Universität Medizinische Fakultät, Kiel		(1923)	75
Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin		(1922)	77, 80
Julius-Maximilians-Universität Medizinische Fakultät, Wurzburg		(1908)	76
Ludwig-Maximilians-Universität Medizinische Fakultät, München		(1934) 79, (1936)	78
Magyar Királyi Erzsébet Tudományegyetem Orvostudományi, Pecs		(1923)	76
Regia Università degli Studi di Roma. Facoltà di Medicina e Chirurgia		(1936)	77

School	FAILED	Year Grad.
Medizinische Fakultät der Universität Wien		(1923), (1936)
Regia Università degli Studi di Roma. Facoltà di Medicina e Chirurgia		(1933)
State Institute of Medical Science, Leningrad		(1924)

Twenty physicians were successful in the practical examination for reciprocity and endorsement applicants held in Chicago, January 26. The following schools were represented:

School	PASSED	Year Grad.	Reciprocity with
Stanford University School of Medicine		(1931)	California
Keokuk Medical College, College of Physicians and Surgeons, Iowa		(1906), (1907)	Iowa
State Univ. of Iowa College of Med.		(1925), (1934), (1936)	Iowa
University of Louisville School of Medicine		(1934)	Kentucky
Louisiana State University Medical Center		(1937)	Louisiana
Johns Hopkins University School of Medicine		(1923)	Maryland
St. Louis University School of Medicine		(1937)*	Missouri
Washington Univ. School of Medicine		(1933), (1934), (1935)	Missouri
Creighton University School of Medicine		(1934)*	Nebraska
University of Nebraska College of Medicine		(1921)	Nebraska
Western Reserve University School of Medicine		(1914)	Ohio
University of Pennsylvania School of Medicine		(1932)	Minnesota
McGill University Faculty of Medicine		(1922)*	Penna.
Universität Heidelberg Medizinische Fakultät		(1923)	Iowa

School	PASSED	Year Grad.	Endorsement of
University of Michigan Medical School		(1937)*	N. B. M. Ex.

Book Notices

Iodine and the Incidence of Goiter. By J. F. McClendon, Professor of Physiological Chemistry, University of Minnesota, Minneapolis. Cloth. Price, $5. Pp. 126, with 64 illustrations. Minneapolis: University of Minnesota Press; London: Oxford University Press, 1939.

After years of research and travel, Dr. McClendon has compiled, from many sources, a vast fund of information concerning iodine and its relation to the incidence of goiter throughout the world. This book represents a tremendous amount of work both in his iodine determinations in this country and in the statistical research on determinations made elsewhere. He has made available, within a few pages, all recent statistical information concerning the well known goiter regions, together with historical data, personal impressions and letters of scientific observations covering many centuries. Briefly, he has given the geographic distribution of this age old disease. The real value of this book lies in the seventy-nine carefully prepared tables and the splendid maps and illustrations. These cover the sources of iodine throughout the world, the variations in iodine content in fruits, grains and vegetables grown in various locations and the concomitant incidence of goiter. This material is vivid and concise and should serve as valuable reference material as to both the distribution of iodine and the incidence of goiter. The treatise on the determination of iodine is excellent and the author's method of determination is still widely used. His original investigations, from 1920 to 1924, on water analysis to determine the available iodine in any community, gave scientific support to the goiter prevention movement. The theory of iodine deficiency is the basis of this prophylactic measure. His efforts in getting accurate data, showing the distribution of iodine throughout this country and obtaining the best authoritative determinations from many lands, are a definite contribution. In general they show as nothing else could the correlation of the deficiency of iodine and endemic goiter.

Allgemeine und besondere urologische Diagnostik beim Jungkind. Von Prof. Dr. C. Noeggerath, Leiter der Universitäts-Kinderklinik in Freiburg i. Br. Die Urologie in Einzeldarstellungen. Herausgegeben von Professor Dr. H. Boeminghaus. Boards. Price, 2 marks. Pp. 32. Leipzig: Georg Thieme, 1939.

This article deals with general and special urologic diagnosis in the case of children. A brief historical review of the subject is presented. It is interesting to note the statement that the year 1929 marked the birth of real interest in this subject in Germany, which began with the use of intravenous urography. Interest has been keen and widespread in the United States for the last thirty years. The author thinks the hesitation to develop the field of urology with reference to children was due probably to the fear of the child and his reaction to instrumentation. The difficulty in focusing attention on the urinary tract has been emphasized many times by many authors, and Noeggerath, as others have done, mentions the fact that the general symptoms are often difficult to interpret and often lead one astray. Attention is called to the fact that severe disease of the urinary tract may be present without either local or general symptoms. Acute pyuria is often confused with grip. During the early stages urinary evidence may be absent. The author points out that tumors in children have no localizing symptoms for a long time, that cachexia occurs very late in the course of the disease and that hematuria is uncommon. Pain and urinary symptoms are difficult to evaluate in the first two or three years of life. Attention is called to the fact that severe pyuria is often present without fever. The various special methods of examination are considered in a systematic manner, the author taking up in turn routine x-ray films, intravenous pyelograms, instrumental examination of the urethra and bladder with sounds and bougies, cystoscopic examination, ureteral catheterization and retrograde pyelograms. The limitations and technical difficulties are stressed. Although he mentions surgical exploration and discusses it briefly, the procedure is rarely employed in this country today. The author emphasizes the great importance during these various examinations of keeping the child warm, a point that is often overlooked. The younger the child the more care should be taken to protect it against the loss of body heat. The subject of anesthesia is discussed briefly. The author does not believe that patients with acute involvement should automatically be examined with instruments, because so many of them recover. Many acute attacks of pyuria run their course in six or eight weeks. The subject of chronic pyuria is fully discussed. The author makes a strong plea for early diagnosis, for only by this means can early treatment be instituted. The necessity for teamwork between practitioner, pediatrician and urologist is emphasized.

Fundamentals of Dentistry in Medicine and Public Health. By John Oppie McCall, D.D.S., F.A.C.D., Director, The Murry and Leonie Guggenheim Dental Clinic, New York City. With a foreword by Wilson G. Smillie, M.D., Professor of Public Health and Preventive Medicine, Cornell University College of Medicine, New York. Cloth. Price, $2.75. Pp. 161, with 50 illustrations. New York: Macmillan Company, 1938.

There is but little justification for the hearty and generous endorsement of this book included with other matter in the foreword. The crude drawing reproduced in figure 1 is perhaps symbolic of the work as a whole. This is a longitudinal and not a "cross section"; even a hasty comparison of it with the very accurate illustration of a similar tooth section in the Spalteholz Anatomy (vol. 3, p. 485) reveals its many serious inaccuracies. A satisfactory presentation of the relationships of the teeth to the jaw structures cannot be shown in a single illustration. Cross sections of tooth roots could have been used advantageously, as well as illustrations depicting the position of the tooth roots with reference to the maxillary sinus, the mandibular canal and the mental foramens. Debatable concepts are introduced as accepted facts, such as that hypoplasia of deciduous teeth is a relatively common occurrence, that Hutchinson's teeth are considered a reliable index of hereditary syphilis and that impacted teeth are primary foci of infection. The choice of authorities cited is questioned on the basis both of omission and of inclusion. On the other hand, some of the illustrations are excellent, notably those taken from Kronfeld and many of the reproductions of roentgenograms. Of the twelve chapters, the first four are concerned largely with the anatomic and embryologic background, the next three with dental caries and related matter, the next three with pyorrhea, gingivitis and focal infection, and the last two with the economic and social aspects of dental practice and dental disease. On the whole this book in its present form cannot be recommended for use by physicians and medical students, even though its many obvious defects are in part balanced by the generally excellent chapters on focal infection, dental care for special groups and dental disease with reference to public health.

Sensible Dieting and the Engel Vital Calorie Diets. By William Engel, M.D. Cloth. Price, $2.50. Pp. 408. New York & London: Alfred A. Knopf, 1939.

In the foreword the author defines himself as "father of a hornet's nest of fads" and accidentally the formulator of the "Hollywood diet." The book is readable if one can tolerate the nonsense neatly sandwiched in. The newly propounded concepts are not only without sound physiologic basis but are in many instances definite misstatements. If taken seriously by intelligent adults, the volume is apt to upset their faith in medical science.

"It is true that shortly after drinking a glass of water the weight may be increased by as much as a pound, but this increase is only temporary" (page 79). Who could be so gullible as to think that "shortly after drinking a glass of water the weight may be increased by as much as a pound"? Is it not still true that "a pint's a pound the world around?" If ingestion of 8 ounces of water results in a one pound increment of weight, why is the effect not immediate rather than "shortly"? "Her loss of weight was so rapid that she became the talk of Hollywood. 'How do you do it?' she was asked by her movie colleagues. 'Simple,' said she; 'I eat lamb chops and pineapple.' The words spread like magic. Few thought it worth noticing that the girl had also been admonished to drink one to three quarts of water before each meal to ease the kidney strain of her high protein diet" (page x). According to what physiologist is one "admonished to drink one to three quarts of water before each meal to ease the kidney strain of a high protein diet," which in the instance cited consisted of "lamb chops and pineapple"?

"Incidentally, a glass of beer contains only 40 to 60 calories while a drink of liquor or a cocktail contains 300 to 450. So beer, much like water, is not fattening between meals, but is very much so between mouthfuls" (page 16). How comes it that beer (erroneously stated to contain "40 to 60 calories"—actually an 8 ounce glass rates 100 calories) "much like water, is not fattening between meals, but is very much so between mouthfuls"?

Even the veriest tyro might wince at the chemical nightmare that stalks through the book. "Starch and water are the chemical equivalent of fat. That is why it is not good to drink water with your meals" (pages 15 and 55). "In any event minimize this danger by toasting your bread and baking your potatoes. This converts the starch into dextrose—the first process of digestion—thereby avoiding the fat-producing danger of undigested starch and also, happily, reducing the calorie content by 40 per cent" (page 16). According to reputable analysis, a slice of white bread weighs 25 Gm. and furnishes 65 calories; toasted it loses 8 Gm. of water, which reduces its caloric content not one whit. But then the adherent of "Sensible Dieting" would not be eating white bread, since it "is neither an energy food nor a body-building food. It is deficient in every dietary factor except starch" (page 32). He (or, more probably, she) would be devouring whole wheat bread, since it is calculated to make one successful in love (page 61).

"Acids like tomato juice and citrus fruits are, paradoxically, alkaline in reaction, if taken at the beginning of a meal. This is because their presence in the stomach inhibits the flow of the acid gastric juices. In other words, they alkalize in a negative way by preventing over-acidity. At the end of a meal, however, these fruits are acid in reaction because they merely add acid to a stomach already amply acidified" (page 38). For the enlightening of the author, neither tomato juice nor citrus fruits are alkaline, having a p_H ranging from 4.0 to 4.3 and 2.0 to 4.0 respectively.

"Roast beef is equally digestible whether rare, medium, or well done. Hamburger steak and stewed, dried, and corned beef are digested as quickly as roast beef, but produce more

acidity" (page 39). This must be some new propaganda. "Meat has sixteen amino acids. Cheese has ten fatty ones. These two groups of acids are incompatible. When mixed in the stomach they cause gas, distention, and acute digestive distress" (page 36). This is plain misstatement.

"In simpler terms, meat once a day (the average portion contains 3.5 ounces of proteins) with the usual amount of milk, eggs, and vegetables, is ideal" (page 47). If one accepts the average portion of meat to contain 3½ ounces of protein, it must be assumed that the individual is to eat pretty close to three fourths of a pound of meat a day. The high protein protagonist should feel elated with the author's recommendation, for if 100 Gm. of protein is to come from the meat it will be very easy to have an intake of 150 Gm. or more when the protein of eggs, vegetables and milk is computed.

"Calcium deficiencies may exist for many years before making themselves evident in nervous disorders. That makes it imperative for adults as well as children to include rich calcium foods—especially milk—in their daily diets. Not only is the milk the richest of calcium foods, but the body absorbs more calcium from milk than from vegetables of equal calcium content" (page 51). Contrary to the popular conception, milk is not a rich source of calcium, as it ranks about twenty-eighth in a list of foods highest in calcium. Milk, however, is an excellent vehicle for calcium, as its volumetric ingestion is so large.

"The danger for the reducer is more one of deficiency because virtually all fad diets omit those essential calcium foods, milk, cream, and cheese" (page 52). Cream is never considered rich in calcium.

"Also it develops a thirst for water, which when taken during meals, as previously explained, combines with starch to make body fat" (page 55). This appears to exploit some of the author's newer chemistry. "But prolonged heating in open pots destroys A and C, changes B into G, does not affect D, E, and G. B, C, and G are soluble in water" (page 58). To date there is no evidence that vitamin B can be changed into vitamin G. This change would be similar to transmutation of metals. "That is why milk is called the perfect food, and eggs are near perfect" (page 71). The reviewer is not familiar with the fact that eggs are a "near perfect" food. "If the extent of acidosis is carefully watched, short repeated fasts may be safely used in the reduction of obesity" (page 87). Such a proposed practice must be heartily condemned.

At least the reader might expect the author of a book on dieting to know that the small calory of physics is not the calory of the nutritionist.

Appended to the volume is a 100 calory portion food table which is full of inaccuracies.

No reviewer would be permitted space enough to justify these diatribes, but the book is limitless in its supply of objectionable or ludicrous data. One wonders what reservoir of knowledge could have been tapped to provide the "facts" which course through the ninety-eight pages of continuity. Neither the 280 pages of diets nor the appended 100 calory portion food table can be commended. No semblance of bibliographic data is presented to substantiate the bizarre "facts."

Medizinische Praxis: Sammlung für ärztliche Fortbildung. Herausgegeben von Prof. Dr. L. R. Grote, leitender Artz der medizinischen Klinik des Rudolf-Hess-Krankenhauses Dresden, Prof. Dr. A. Fromme, Direktor der chirurgischen Abteilung des Stadtkrankenhauses Dresden-Friedrichstadt und Prof. Dr. K. Warnekros, Direktor der staatlichen Frauenklinik zu Dresden. Band XXVII: Die peripheren Durchblutungsstörungen. Von Dr. med. habil. *M. Ratschow, Dozent für Innere Medizin a. d. Martin-Luther-Universität Halle a. S.* Mit einem Geleitwort von Prof. Dr. R. Cobet, Direktor der medizinischen Universitäts-klinik Halle a. S. Paper. Price, 9.75 marks. Pp. 193, with 46 illustrations. Dresden & Leipzig: Theodor Steinkopff, 1939.

This is the twenty-seventh volume of a series of monographs written for the general practitioner. It is the first German treatise on the disturbances of peripheral circulation and, as the author himself has stressed, leans heavily on Sir Thomas Lewis's classic description of the vascular disorders of the limbs. It is a short concise exposition of the present day status in this field. Certain statements may seem stimulating or controversial to the American reader, such as that large epidemics are followed by a marked increase in Buerger's disease, that insulin produces vasospasm, edema and hemorrhages and that lack of the insulin-free pancreatic extract may be the cause of the peripheral circulatory failure in diabetes, that small doses of ergotamine (0.05 mg.) are useful in the treatment of vasospasm, that large doses of androgenic and estrogenic substances are to be administered to men and women respectively for their vasodilating effect, that procaine acetylcholine infiltration of gangrenous parts gives relief from pain and that irradiation of sympathetic ganglions has a beneficial effect on peripheral circulation. The author is best known from his extensive studies on the visualization of blood vessels, and many excellent films are shown. He is not afraid of colloidal thorium dioxide, like several men in this country, but all the late effects of this radioactive substance have not been reported. The general practitioner has nothing to gain from a perusal of this monograph, as there are excellent books on peripheral circulation in English. For the man interested in this field it will give a somewhat rigid, dogmatic exposition of nothing new on the subject.

Diet Manual of the Mount Sinai Hospital, New York City. Third edition. Paper. Pp. 131. New York, 1939.

This loose leaf manual of the diets used at Mount Sinai Hospital, New York, is printed in readable type with wide margins. It includes height and weight tables and a table of the approximate measures of numerous foods that make up 100 Gm., with the number of calories for each food and the percentage of carbohydrate, protein and fat. Among the many diets outlined, with rules for using them, are the low calory diet, high calory diet, Sippy diet, low residue diet, low salt diet, alkaline-ash diet, elimination diets, diabetic diets and infant feeding diets.

Occupation Hazards and Diagnostic Signs: A Guide to Impairments to be Looked for in Hazardous Occupations. (Revision of Bulletin No. 306.) By Louis I. Dublin, Ph.D., Third Vice President and Statistician, and Robert J. Vane, Supervisor of Occupational Ratings, Metropolitan Life Insurance Co. United States Department of Labor, Bureau of Labor Statistics, *Bulletin No. 582. Paper. Price, 10 cents. Pp. 52. Washington, D. C.: Supt. of Doc., Government Printing Office, 1933.*

The third edition of this bulletin has been reissued to meet a steady demand. Nine hundred occupations, actually or potentially hazardous to the health of workers, are listed alphabetically. The hazards themselves are arranged according to a useful classification whereby symptoms, occupations in which they occur and methods of prevention are correlated. There is also a partial list of skin irritants identified with certain occupations. Physicians will find it time saving to consult this useful compilation as an introduction to more extended treatment in the standard textbooks on industrial health in the study of cases in which occupation is suspected as a contributor to poor health.

Hospital Libraries. By E. Kathleen Jones. Cloth. Price, $2.50. Pp. 208, with 8 illustrations. Chicago, Illinois: American Library Association, *1939.*

This book is designed especially for younger hospital librarians with the hope that it may solve some of their problems and guide them in their service to the medical and nursing professions as well as in the service of those patients who require "bibliotherapy." In discussing books and therapy, the author suggests excluding certain types of books, and to do this the hospital librarian must have the interest and cooperation of the physician, the occupational therapist and the medical social worker. Interloan services between hospital and other libraries in the community are described. After a full discussion of the organization of hospital libraries, the author emphasizes the importance of professional libraries and the physician's greater reliance on current periodicals rather than on books. She also stresses the need for indexes, notably the *Quarterly Cumulative Index Medicus.* The development of hospital libraries and their present and future importance apparently depends on recognition of the fact that trained library personnel is the first essential of a useful library, whether it is situated in a hospital or elsewhere. The appendixes will be helpful to librarians.

Beauty Plus: The Smart Woman's Key to Beauty, Health and Charm. By Mary MacFadyen, M.D. Cloth. Price, $1.96. Pp. 272, with illustrations by Frank N. Netter, M.D. New York: Emerson Books, Inc., 1938.

The author of this volume seems to have caught the idea of making sound hygiene attractive. The book is cleverly illustrated and is a most interesting volume of general advice for women on health, beauty, recreation and the sex life.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospitals: Liability for Injury to Patient from Fright Caused by Defective Electric Fan.—In a suit against the defendant, a hospital operated for profit, the patient in her petition alleged that, as the result of fright and shock caused by the flying apart and "exploding" of a defective electric fan in the room occupied by her at the hospital, she suddenly jerked or jumped in bed, tearing out the sutures which had been inserted in an operation for "an abscessed fistula in ano." Her petition alleged further that, as a result of the defendant's negligence, there developed an infection at the site of the operation, a recurrence of the fistula necessitating further surgical treatment, and also a focal infection of her kidneys, known as Bright's disease, with associated impairment of her eyesight. The trial court dismissed her petition as not stating a cause of action but, on appeal, the court of appeals of Georgia, division 1, reversed the judgment of the trial court. In holding that the petition did state a cause of action, the court of appeals said that a hospital conducted for private gain owes its patients the duty of exercising in their behalf "such reasonable care and attention for their safety as their mental and physical condition if known may require."—*Garner v. Newnan Hospital (Ga.), 198 S. E. 122.*

Workmen's Compensation Acts: Incapacity Due to Tuberculosis Following Trauma.—The employee in this case had had tuberculosis for many years but, according to his petition, "it had caused him no trouble or discomfort." In the course of his employment in 1933 he fell against a ladder and, as a result, he claimed, his tubercular condition was activated to such an extent that, two years later, he became totally incapacitated. He filed a claim for compensation under the Texas workmen's compensation act which was disallowed by the industrial accident board. The district court on appeal entered a judgment in the employee's favor and the employer's insurer appealed to the court of civil appeals, Texas.

There was no evidence, the court said, to warrant the inference that the employee's tubercular condition was no longer active at the time of the accident. Since it was admitted that the employee had had active tuberculosis prior to the injury and that approximately two years after the injury he had "tuberculosis in a far advanced state," there existed a presumption that the disease had continued from long prior to the injury. When tuberculosis is authentically established, the court pointed out, it is presumed to continue until rebuttal evidence is produced, or an occasion arises for the application of a contrary presumption. The presumption to which the employee's own pleading and evidence gave rise, that is that he had active tuberculosis from long prior to his injury, was, the court said, rebuttable but there was no evidence tending to rebut the presumption. The testimony of one physician was supposed to have a bearing on this point and to be favorable to the employee. His testimony, however, was based on the assumption that at the time of the accident the employee "was strong and healthy." Such an assumption was unsupported by evidence. With the fact presumed against the employee that he had active tuberculosis at the inception of the injury, the conclusion seemed inescapable to the court that there was a total absence of evidence to raise an issue of the fact that but for the accidental injury the employee's incapacity from tuberculosis would not have resulted.

The court disclaimed any intention of holding that, if the employee already had active tuberculosis at the time of his injury, the fact that his subsequent incapacity resulted from tuberculosis would, as a matter of law, show that he had no right to compensation. On the contrary, the law was recognized to be that recovery of compensation will not be denied "although it may appear that the injury received was aggravated by the effect of some disease existing at the time of the injury or occurring afterwards." *Guzman v. Maryland Cas. Co.* 107 S. W. (2d) 357. The question before the court was one not of law but of the existence of evidence to warrant a particular finding. The employee had the burden of showing by a preponderance of the evidence that the incapacitating tuberculosis was a part of his accidental injury, which of course the tuberculosis he already had at the time of the injury was not. According to his testimony, it was "three or four months" after the accident that he noticed a little hacking cough. That was also after he had undergone a herniotomy. It was not even shown, the court pointed out, that the employee had not taken ether in connection with the herniotomy. There was simply no evidence that the court could find tending to differentiate disease which was no part of the alleged injury from disease which was a part of such injury. Every fact in evidence, the court concluded, which might indicate that the accident had any influence whatever on the preexisting disease seemed equally referable to the natural progress of the disease.

For the reasons stated, and for the further reason that the employee had failed, without legal excuse, timely to file his compensation claim, the judgment of the district court for the employee was reversed.—*Safety Casualty Co. v. Walls (Texas), 117 S. W. (2d) 879.*

Taxes: Validity of Municipal Occupational Tax.—The City of Tampa, Fla., in exercise of power granted to it by its charter to license professions, businesses and occupations, imposed by ordinance an annual license tax of $60 on physicians and certain other professions. Subsequently, a state statute was enacted imposing an annual state license tax of $10 on professional men and, except as otherwise provided or authorized by law, imposing an additional county tax of 50 per cent of the state tax and authorizing incorporated cities and towns to impose further license taxes not to exceed 50 per cent of the state tax. The state, on the relation of certain persons engaged in the practice of medicine, law and certain other professions in the city of Tampa, brought original proceedings in the Supreme Court of Florida for a writ of mandamus to require the city tax collector to issue occupational licenses to the relators on the payment of $5 each or 50 per cent of the $10 state license tax, claiming that the state statute prohibited the city from imposing any license tax on the practice of the several professions in excess of $5 per annum. The Supreme Court, however, held that the legislature, by enacting the state statute, had not intended to repeal the prior city ordinance imposing the municipal license tax of $60 passed pursuant to authority conferred by the city's charter. In the judgment of the court, the state statute was intended only to place a limit on license taxes in those municipalities not already authorized by law to impose a greater tax. Accordingly, the petition for a writ of mandamus was denied.—*State ex rel. Holloway et al. v. Keller (Fla.), 182 So. 779.*

Society Proceedings

COMING MEETINGS

American Association for Thoracic Surgery, Los Angeles, July 5-7. Dr. Richard H. Meade Jr., 2116 Pine St., Philadelphia, Secretary.

American Physiotherapy Association, Denver, June 25-30. Mrs. Eloise T. Landis, 2065 Adelbert Road, Cleveland, Secretary.

American Proctologic Society, Brooklyn, N. Y., June 25-27. Dr. Curtice Rosser, 710 Medical Arts Bldg., Dallas, Texas, Secretary.

Maine Medical Association, Poland Springs, June 25-27. Dr. F. R. Carter, 22 Arsenal St., Portland, Secretary.

Medical Library Association, Newark, N. J., June 27-29. Miss Janet Doe, 2 East 103d St., New York, Secretary.

Montana, Medical Association of, Butte, June 28-30. Dr. Thomas L. Hawkins, 50 North Main St., Helena, Secretary.

National Tuberculosis Association, Boston, June 26-29. Dr. Charles J. Hatfield, 50 West 50th Street, New York, Secretary.

Pacific Coast Oto-Ophthalmological Society, San Francisco, June 19-22. Dr. C. Allen Dickey, 450 Sutter St., San Francisco, Secretary.

West Virginia State Medical Association, White Sulphur Springs, July 10 12. Mr. Joe W. Savage, Public Library Bldg., Charleston, Executive Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Cutaneous Diseases of Extremities and Their Relation to Surgery. C. S. Wright and J. P. Guequierre, Philadelphia.—p. 322.

Dashboard Fractures of Patella.—After reviewing twenty-six cases of severe injury to the patella, Ferciot is impressed with the thought that the function of the patella in protecting the extensive articular cartilage of the lower end of the femur from direct trauma deserves more consideration than it has been accorded. Projecting forward as it does in the intercondylar space, the patella forms an excellent buffer mechanism for the knee joint, particularly in the flexed position. Without its protection, a large portion of the articular surface of the femur would be exposed to the insult of repeated injury. The fact that this bone exhibits extremely low reparative powers lends further credence to the impression that its function is largely protective and that it has been adapted to perform this function. If it possessed high osteogenic powers, the repeated trauma to which it is continually subjected would result in extensive proliferative changes, which would soon have a deleterious effect on the knee joint itself. In the present series twenty of the twenty-six cases could be traced. In six cases treated by external fixation the period of disability averaged 10.65 weeks. Of the six treated by open operation and fixation the average period of disability was 17.65 weeks. In the eight cases of comminuted fractures treated by excision and primary suture of the remaining fragment to the extensor apparatus, the average disability was 10.75 weeks. All of the six cases treated by casts alone had good functional results, of those treated by open reduction and fixation four had good results and two only fair, and of the eight cases of comminution treated by excision and primary suture all showed good end results. In no instance was it felt necessary to excise the entire patella, although in certain cases of severe comminution this procedure might be warranted. Proper after-care is of the utmost importance. The presence of the patella, although adding little to the mechanical efficiency of the knee, exerts a beneficial protecting influence and its preservation is urged whenever possible. Excision of fragmented portions of the bone, followed by suture of the extensor ligaments to the remaining fragment, retains this protective function and shortens the period of disability that follows dashboard fractures.

Tuberculosis of Tonsils.—Long and his associates examined microscopically for tuberculosis 2,000 unselected pairs of tonsils surgically removed. One half of these tonsils came from various Indian reservations, known to be communities of high tuberculosis morbidity; 600 from Puerto Rico, a region with much tuberculosis but of a lower morbidity than that of the Indian reservations, and 400 from Philadelphia, a community of low tuberculosis morbidity in comparison with the other two. Tuberculosis was found in eighty-one pairs of tonsils; that is, tuberculous tonsils were found in 6.5 per cent of the tonsils from the Indian reservations, 2.5 per cent of those from Puerto Rico and 0.25 per cent of those from Philadelphia. Roentgenograms of the chest were secured in thirty-five of the eighty-one instances in which tonsillar tuberculosis was present. Active pulmonary tuberculosis of the adult type was found in sixteen and active tuberculosis of the childhood type in two. In general, the tonsillar lesions in this group were cryptal and were more extensive than those in the rest of the thirty-five cases; on the basis of pathologic appearance the tonsillar tuberculosis was believed to have resulted from direct infection by the bacilli contained in the sputum from the associated pulmonary lesion. All stages of regression of tonsillar tuberculosis from active fibroplastic disease to scars indistinguishable from scars of other origin were seen in the series. The relatively massive tuberculosis of the tonsils in cases of pulmonary tuberculosis, its tendency to be bilateral and its chronicity all point to repeated infection of the tonsils in the course of the pulmonary disease. There is reason to believe that at some time or other the majority of patients with progressive pulmonary tuberculosis, if not all of them, have tuberculosis of the tonsils.

Sedimentation Rate in Chronic Illness.—Stiles observed the sedimentation rate and nuclear count of 292 patients with chronic or frequently recurring symptoms which were suspected of being secondary to low grade chronic infection. Of this number 277 showed evidence of either chronic sinusitis or chronic nasopharyngitis. There were fifty-two patients with chronic bronchitis, seventy-five with symptoms referable to the biliary tract, seventy-eight with gastrointestinal conditions, thirty-six with symptoms referable to the urinary tract, forty with arthritis and thirty-six with "rheumatism." The mean sedimentation rate (Westergren) for all patients was 15.9 mm.; the mean nonfilament-filament ratio was 25.2. The mean sedimentation rate for women was higher than that for men, but there was no variation in the nonfilament-filament ratio. There were no

significant variations when the sedimentation rates and nonfilament-filament ratios were distributed according to age (the extremes in the patients examined were 2 and 80 years), except for a possibly significant increased sedimentation rate in the group of patients more than 60 years of age. When the changes found were distributed according to disease, there were only questionable variations, except for colitis (high nonfilament-filament ratio), duodenal ulcer (low sedimentation rate) and rheumatoid arthritis (high sedimentation rate and nonfilament-filament ratio). When the observations were distributed according to severity of symptoms, there was a direct relationship; as symptoms increased the sedimentation rate and nonfilament-filament ratio increased. When symptoms were more or less acutely exacerbated the nonfilament-filament ratio was high, but the sedimentation rate was relatively low. The nonfilament-filament ratio appears to be a more sensitive indicator of the presence of disease than the sedimentation rate, although the readiness of its response to acute exacerbation makes the finding of an increased sedimentation rate of more significance in the diagnosis of chronic illness than the finding of an increased nonfilament-filament ratio.

Amphetamine Sulfate and Gastrointestinal Activity.—Beyer and Meek present studies concerning the influence of amphetamine on the initial and final gastric emptying in ten medical students and evidence from animal experimentation on the manner in which this effect is produced. In man amphetamine sulfate was found to decrease the time for initial emptying of the stomach to about 42 per cent of the observed normal and to increase the average time for final emptying 21 per cent. The decrease in the initial emptying time of the normal stomach following administration of amphetamine is probably due to the primary increase in tonus and activity of the stomach raising intragastric pressure and forcing the contents through a pylorus the tonus of which, if altered by the drug, may relatively be only slightly increased, rhythmicity being correspondingly diminished. The delay in final emptying is due to secondary inhibition of the stomach and possibly increased pyloric tonus. While the stomach does not fully recover from the secondary inhibition for more than an hour, final emptying is not prolonged to a significant extent. Only by using excised intestinal strips and concentrations unapproachable in the normal animal could any effect of the drug on the intestine be demonstrated. The results suggest that what value amphetamine has in overcoming functional pylorospasm of a moderate degree is probably due to initial gastric stimulation overcoming pyloric resistance rather than to any direct inhibiting effect on pyloric tonus.

Treatment of Disturbed Patients with Sodium Chloride.—By the use of sodium chloride, either by mouth or by intravenous injection of physiologic or hypertonic solutions and by forcing fluids, Bowman and Keiser have been able to decrease the death rate of excited and disturbed patients with mental disease. Patients with both organic and functional disturbances and alcoholic delirium were treated. This method of treatment also shortened the period of excitement. Fever due to dehydration was prevented or successfully treated by this method. In considering how to treat these patients, the authors decided that edema of the brain, which is present at times, should be disregarded and that treatment should be only for acidosis and dehydration. Fluids were forced and the patients were given 1 Gm. capsules of sodium chloride every four hours to help retain the fluids. Fluids were forced in the form of orange juice, with one tablespoonful of sucrose to each glassful. In a period of six months prior to this form of treatment there were ninety-two cases of alcoholic delirium, in sixteen of which death resulted from alcoholism. During the following eight months all alcoholic patients in the ward for disturbed patients were treated with capsules of sodium chloride and orange juice and of thirty-seven cases of delirium there were three deaths due to alcoholism. During the following four months the authors gave the treatment on alternating weeks to the alcoholic patients admitted. During the weeks when patients were not treated with sodium chloride they were subject to ward routine and fluids were forced. Among the treated patients there were no deaths, and of the untreated patients two died. In the untreated patients the average time required for the delirium to clear was six days during the first period of control and four days during the second period of control, whereas the treated patients required an average of 2.5 days. The authors' rationale for treatment with salts and fluids was based on the fact that the patients were suffering from systemic acidosis and dehydration. Patients fed by mouth instead of intravenously do better and there is no danger to the circulatory system; but, if patients remained uncooperative, medication was employed and the fluids were given through a Levine tube. The patients who recovered included those who were admitted with temperatures as high as 105 and 106 F. Of twenty-two patients with dehydration due to schizophrenia, manic-depressive psychosis and dementia paralytica not given the authors' treatment eight died, but of fourteen patients with similar conditions given two capsules of sodium chloride every four hours and physiologic solution of sodium chloride none died. The average duration of fever in these patients, on the basis of one reading a day, was 1.5 days. In another group of thirteen patients who had fever due to dehydration, the average duration of the fever was 1.7 days. Of these patients, eight had fever on admission and three had an elevation of temperature at one reading. Three of these patients died. One, with schizophrenia, had a temperature of 105 F. on admission. Another patient with schizophrenia was admitted with a temperature of 102 F. and died six days later. The third patient had dementia paralytica, with a temperature of 103 F. on the fifth day, and died two days later. Roentgenographic examination revealed extensive pneumonic consolidation of both lungs. Thus, by the use of sodium chloride there has been an abrupt drop in the duration of fever due to dehydration and a marked decrease in mortality due to exhaustion.

Abolition of Tremor by Surgical Means.—The demonstration by Aring and Fulton that intention tremor resulting from cerebellar lesions can be abolished in subhuman primates by the removal of the precentral cortex (areas 4 and 6 of Brodmann) led Bucy and Case to attempt to relieve a similar incapacitating tremor in a man. The much older observation that the tremor at rest in patients with parkinsonism is abolished, at least for the duration of the paralysis, by a temporary hemiplegia gave rise to the hope that the tremor at rest also present in this patient would be abolished by a precentral extirpation. Both the tremor at rest and that appearing on voluntary movement, which developed after severe cerebral trauma, were abolished (and has not returned after fifteen months) by removal of the precentral "arm" area.

Picrotoxin as Convulsant for Mental Illnesses.—In a group of thirty-eight patients (schizophrenia, manic-depressive psychosis and psychopathic personalities) Low and his colleagues produced convulsions by means of intravenous injections of picrotoxin. Because of the interval between the injection and the first convulsion and that between the first and subsequent convulsions the action of both the drug and the convulsions can

be conveniently studied. Picrotoxin does not produce the terror incidental to metrazol. Of the nineteen schizophrenic patients, with a long average duration of the disease, five made a full recovery. As with metrazol medication, the manic-depressive attack in eight cases was cut short with relative promptness and the severe psychoneuroses of seven patients responded satisfactorily. Of the four patients with disturbed behavior requiring commitment, two recovered fully and one had a social recovery. Of the total of eighteen fully or socially recovered patients, three have maintained their health for five months, seven for four months, three for three months and five for less than three months; none have relapsed to date.

*Controlled Study of "Cold Vaccines." I. J. Hauser and M. J. Hauser, Detroit.—p. 704.
Peroral Endoscopy. L. H. Clerf and F. J. Putney, Philadelphia.—p. 720.

"Cold Vaccines."—In their controlled study of the value of "cold vaccines" the Hausers gave cold vaccine subcutaneously to the first ten persons, intradermally to the next ten and placebos to the following ten. This cycle was repeated until there were 100 persons in each group. After this number was reached the vaccine was given subcutaneously to the next hundred who presented themselves at the clinic for treatment. The first injections were given during the third week in October and the last ones by the middle of December. During the last two weeks in May each student who had received the injections was interviewed, provided he had completed the series. Data were obtained from 188 persons who had received the vaccine subcutaneously, from ninety-five who had received it intradermally and from eighty-six to whom placebos had been given. Of the persons who had received the vaccine subcutaneously, 74 per cent said that they had had fewer colds, 6 per cent that they had no colds at all, 18 per cent that they had the same number as during the preceding year and 2 per cent that they had more colds. Of those who had received the vaccine intradermally, 52.6 per cent reported that they had had fewer colds, 11.6 per cent that they had no colds at all, 32.6 per cent that they had the same number as before and 3.2 per cent that they had more colds. Among those who had received placebos, 60.5 per cent reported that they had had fewer colds, 5.8 per cent that they had no colds at all, 31.4 per cent that they had the same number as the last year and 2.3 per cent that they had more colds. More than 90 per cent of all the subjects expressed a desire to be similarly treated the following year.

Sulfanilamide in Experimental Pneumococcic Infections.—Greey and his associates found sulfapyridine superior to three other sulfanilamide compounds in experimental type I pneumococcic infections in mice. A high survival rate was obtained in such infections with sulfapyridine when it was administered so as to maintain the blood concentration of the drug above 10 mg. per hundred cubic centimeters. Sulfapyridine is at least as active as sulfanilamide in experimental Streptococcus haemolyticus infections in mice. Signs of toxicity were not observed in the mice treated with sulfapyridine but were seen in those treated with two other sulfanilamide compounds.

Sulfanilamide for Cystitis and Pyelitis.—With sulfanilamide in the treatment of cystitis and pyelitis Mitchell and his colleagues obtained results that were unexcelled by any drug used previously in their clinic. They evolved a method of administration which is particularly suited to infections of the urinary tract. The regimen has proved highly satisfactory in treating pyelitis of pregnancy. Patients are given the following simple instructions: (1) to take one tablet (5 grains) after each meal on the first day, two after each meal on the second, three after each meal on the third day and, if necessary, four after each meal on the fourth day, (2) to limit their total fluid intake to the equivalent of about eight glasses of water a day and (3) to void into a clear glass receptacle, to examine the urine for turbidity and as soon as a clear urine is obtained to notify their physician. To prevent relapse, the drug is withdrawn slowly; after four days on the curative dose the total daily intake of sulfanilamide is decreased by 5 grains (0.3 Gm.) every other day until a daily dose of 10 grains (0.6 Gm.) is reached. This dosage is continued for from seven to ten days. This minimal effective step-dosage regimen, the authors state, nearly always produces a sterile urine within from two to four days, provided the infection is not complicated by malformation, neoplasm or stone in the urinary tract. The organisms which respond most readily to sulfanilamide are Bacillus coli, Bacillus proteus and staphylococci. Fecal streptococci are completely resistant. Toxic effects are less frequent and are usually of milder form on the dosage recommended than on other regimens which have been tried.

Cyclopropane.—During 1937 and 1938 Combs gave 700 anesthetics using cyclopropane; 302 were for laparotomies and 398 for extraperitoneal operations. In these 700 anesthesias there was an absence of sweating with a reduction in the loss of water vapor, necessitating fewer subcutaneous injections of fluid. It is superior to nitrous oxide in that it produces no subjective symptoms such as hallucinations or tinnitus aurium.

Meningitis Caused by Atypical Gram-Negative Cocci.—Reimann and Koucky studied the atypical bacteria found in two cases of meningitis. From the first patient, a gram-negative diplococcus with characteristics different from other classified strains was isolated. The bacterium gave rise to two interchangeable colony forms. From the second case, two species of cocci were obtained; one was a type I meningococcus which had the unusual ability to grow on plain agar at room temperature and had gram-positive elements; the other was a staphylococcus which was represented by three interchangeable colony forms. These studies suggest that, under ordinary laboratory routine examination, atypical colonies may appear on culture plates. Such colonies, usually ignored or dismissed as contaminants, may actually be part of the pattern of variation of the bacterium concerned. Recognition of the phenomenon of bacterial variation and type transformation would remove much confusion and would probably reduce the varieties of bacteria now believed to exist.

The Blood in Experimental Poliomyelitis.—Gordon and Lennette tested the blood of monkeys at various stages of experimental poliomyelitis for the presence of virus. This was accomplished by multiple transfusions of blood from inoculated monkeys into normal monkeys, the latter also receiving starch solution intracerebrally. The intracerebral injection of starch has been shown to disrupt the blood-brain barrier and to facilitate infection. Tests for immunity were subsequently done on the recipient monkeys. Virus was not demonstrated in fourteen samples of blood, ranging in volume from 10 to 45 cc., taken from paralyzed monkeys, or in twenty-eight samples, from 8 to 30 cc. in volume, from infected monkeys before paralysis appeared. Repeated intranasal inoculation of seven monkeys after destruction of their olfactory bulbs did not result in a clinical attack of poliomyelitis, in the appearance of virus in the blood or in a detectable immunologic response. No evidence, therefore, was found for the absorption of virus by the blood stream or by other routes from the nasal or alimentary mucosa. The results indicate that poliomyelitis virus either does not enter the blood stream of intranasally inoculated monkeys or it does so in amounts too small to be detected by the methods employed.

Photoallergy, Photosensitivity and Sulfanilamide.—Epstein carried out experiments with sulfanilamide, as a photosensitizing drug, on five volunteers and himself. He found that sulfanilamide produces a primary photosensitivity at the site of intracutaneous injection. The injection of sulfanilamide followed by an erythema dose of ultraviolet rays produced in all (twenty-two) an erythematous reaction of from about 0.8 to 1 cm. in diameter, contrasting with the milder erythema of the surrounding skin. This reaction appeared after from one to twenty-four hours, persisted for several days and led eventually to pigmentation. A different type of reaction appeared in two of the test persons on the tenth day. At this time an inflammatory, urticarial reaction with intense pruritus developed spontaneously at the site of the primary reaction. This latter reaction was considerably larger than the original response but of similar configuration. It persisted from ten to fourteen days This reaction was quite obviously entirely different from the primary one. Every subsequent experiment in the two sensitized persons produced a spontaneous inflammatory-urticarial response, but now this appeared not ten days but from ten to twenty-four hours after the test. The experiments demonstrate a true allergic type of photosensitivity (*photoallergy*). The author believes that this is the first report of this particular type of photosensitization and the first experimental proof of the allergic nature of this form of light sensitivity. More experimental work will be necessary to clarify the relationship of this form of response to various forms of clinical hypersensitivity to light. The photoallergic reaction fulfils

the requirements of a true allergic phenomenon; the capacity to react is produced by a previous contact and is manifested, after a definite incubation period, by an altered and accelerated reaction to a subsequent exposure to the same agents, that is, sulfanilamide plus light. The irradiation of sulfanilamide in the skin produces a substance responsible for the appearance of the primary reaction. Following this reaction, the skin of certain predisposed persons becomes sensitized to this substance.

Metastatic Bone Carcinomatosis.—Ben-Asher cites a case with definite bone metastases associated with parathyroid hyperplasia and with symptoms of hyperparathyroidism. Hypercalcemia was associated with metastatic carcinoma of the bones and with parathyroid hyperplasia. Removal of the hyperplastic parathyroid gland did not reduce the serum calcium to normal, but the calcium level was somewhat lower than before the operation. Lowering of the serum calcium was observed ten days after operation and lasted for about ten weeks, after which there was a slight rise. It seems reasonable to assume that both the osseous destruction and the hyperplasia may have been factors in producing the hypercalcemia, and, as Barr and Bulger suggest, *the osseous changes may have stimulated the parathyroid*, which in turn aggravated the condition. Failure to find another pathologic parathyroid at a second operation does not eliminate the possibility of an abnormally situated one, which would account for the persistence of the hypercalcemia. The author states that the hyperplasia in his case was secondary to the osseous changes. Since removal of the gland resulted in a somewhat lower level of the blood calcium, it is reasonable to conclude that the gland showed evidence of hyperfunction. This would support the theory of Erdheim of compensatory hyperplasia. Compensatory hyperplasia has been found in conditions associated with low serum calcium, such as rickets and osteomalacia, and also in conditions in which the serum calcium is high. Further studies of the physiology of the parathyroids might throw more light on the subject.

Effects of Smoking on Blood Sugar and Temperature.—On the basis of their observations (six healthy students, eleven hypertensive patients and eighteen patients from the medical ward with cardiac decompensation or other diseases), Cates and Giovanazzi conclude that smoking affects the peripheral vascular system less in cardiac convalescents than in young healthy men *who have not been confined to bed*. The older the subject, the less susceptible is his vascular tone. Results obtained in subjects in their second and third decades of life may not by inference be applied to the later decades. The hypertensive group of patients, while smoking, showed no greater variation of cutaneous temperature than occurred during the preceding control period of forty-five minutes. In this group, the highest blood pressure rise was 15 mm., the average 8 mm. In the student group the highest was 35 mm. and the average rise was 19 mm. The third group gave a negative temperature response. Of twenty-four studies only four had a temperature decrease of the toes of more than 1.5 C. Two of twelve had depressed finger temperatures. A composite curve representing twenty-six curves of capillary blood sugar determinations on twenty subjects establishes no elevation of the fasting dextrose values after smoking from two to five cigarets. Artificial elevation of the blood sugars by intravenous injection of 50 cc. of a 50 per cent dextrose solution likewise had no effect on the peripheral temperature.

Vitamin C in Blood During Pregnancy, Birth and Infancy.—Snelling and Jackson measured the ascorbic acid content of the plasma of pregnant women. There seems to be a slight fall toward the end of pregnancy. Factors incident to labor lower the ascorbic acid in the maternal blood. The fetus acts as a parasite and has higher levels than the antepartum

maternal blood. Totally breast-fed infants are well supplied with vitamin C if the ascorbic acid of the breast milk is greater than 4 mg. per hundred cubic centimeters; if the ascorbic acid is below 2 mg. there is a likelihood of a deficiency in the infant. In artificially fed infants not receiving additional vitamin C, the level of ascorbic acid in the blood is low. It is recommended that artificially fed infants should receive additional vitamin C from the time they are 2 weeks of age. The mothers of breast-fed infants should have adequate vitamin C in the diet, and, if there is any question of lack in her diet, the infant should receive additional vitamin C.

Treatment of Cryptorchidism with Gonadotropic Substance.—Zelson states that his work on the treatment of cryptorchidism with gonadotropic substance gives less favorable results, but he feels that his observations, based on rigid criteria, represent a true figure of the best possible results obtainable in carefully selected cases of true cryptorchidism. Only children more than 4 years of age were treated. Twenty-six boys with thirty-four undescended testicles were given the gonadotropic hormone. In eighteen the condition was unilateral. Following treatment, complete descent occurred in eight boys, 31 per cent. Of these cases five were unilateral and three bilateral. The condition was considered as having successfully responded to treatment only when the testicles descended into the scrotum. In the eight successful cases five of the patients responded to less than 5,000 units; six of them responded to treatment within three months. The penis, testicles and scrotum became larger during the course of treatment in every case. Pubic hair developed in a few. On reexamination of the unsuccessful cases, from three to six months after the cessation of treatment, the testicles that had enlarged during treatment had shrunk back to their original pretreatment size. The penis continued to remain large. During the course of the treatment, seven of the twenty-six boys were reported as being "bad boys" in school. When the injections were discontinued, however, this situation improved. Six of the eight successful results were in boys less than 10 years of age. Therefore it appears that treatment should be seriously considered in the earlier age groups despite the prevailing opinion that it should be deferred until the age of 10 or 11.

Massive Vitamin D for Rickets and Tetany.—According to Vollmer, the curative effect of a single shock dose (600,000 international units) of vitamin D orally is more prompt than that obtained by small daily doses. Tetanic convulsions did not recur in 150 children after vitamin D shock therapy, and all other symptoms of hyperirritability usually disappeared within two days. If hypernormal values of serum phosphorus occur after vitamin D shock therapy, they usually decline to a normal level in from two to four weeks. Vitamin D shock therapy is indicated in neonatal and infantile tetany, severe rickets, rickets associated with pneumonia or pertussis, rickets associated with chronic infections and in a rachitic or tetanic child whose parents are indifferent to his condition. No contraindication seems to exist. No toxicity was manifested in the 150 children treated with massive doses of vitamin D. The possibility of a successful vitamin D prophylaxis over the entire winter period with a single dose is discussed.

Syphilitic Epilepsies.—Babalian states that syphilitic epilepsy is not as rare as the majority of authors believe. Hereditary syphilis seems to be a frequent cause of epilepsy and should be sought by every kind of examination, especially by a complete family inquiry. However, in many cases traces of syphilis cannot be discovered; but its possibility must not be ignored. If one considers the dark future of many epileptic persons, one has the right to try a specific treatment in all these cases, because it is better to sin in this instance by commission than by omission. Specific treatment can be effective only at the outset of the disease before the appearance of neurogliac sclerosis. Epilepsy, then, must be treated not when it is evident clinically but in its prodromic stage. This stage, in child epilepsy, is precisely that of the first convulsions in infancy, after which the convulsions cease and are followed generally by a period of deceiving calm. It is too late to give treatment if after several months or even years the first signs of epilepsy appear. The ideal course would be to give specific treatment as soon as the convulsions of infancy occur. However, specific treatment should not be given all persons with convulsions. The cases due to obstetric cranial injuries and those due to toxic infectious diseases must be eliminated. In a certain number of cases in which the nature of convulsions cannot be determined exactly the author believes that one has the right to and should give specific treatment. The problem takes a different form when epilepsy has become evident because of an irreparable lesion. Specific treatment should, however, be tried, less with the hope to improve the disease than to limit the damages. In that case it seems prudent to use only bismuth or mercury, because arsenic, being a strong vasodilator, could precipitate epileptic seizures or even congestive and hemorrhagic lesions in the central nervous system—lesions which epilepsy already tends to produce.

Gout Controlled by Diet.—Bartels shows that gout can apparently be controlled from both the standpoint of symptoms and the level of blood uric acid. His plan of treatment consists in the utilization of a diet high in carbohydrate and low in fat and purine, with the addition of the periodic administration of cinchophen. The diet used is that proposed by Lockie and Hubbard and the cinchophen is given according to the plan of Hench, 7½ grains (0.5 Gm.) three times a day for three days each week. Four cases are reported which illustrate the author's experience with this treatment. The plan prevented further attacks of joint pain and the blood uric acid returned to a normal level. The low-fat, high-carbohydrate diet is not difficult to prepare and its satiety value is satisfactory. The results, he states, warrant further investigation of such a plan in a larger series of patients.

Syndrome Simulating Tabes.—Costello describes a syndrome which although simulating tabes dorsalis with its Argyll Robertson pupil and absent tendon reflexes is essentially different from it. A knowledge of this condition is of importance to the physician who assumes the responsibility of diagnosing and treating syphilis. The pseudo-Argyll Robertson pupil of Adie's syndrome does not react to light either directly or consensually and in this way is identical with the true Argyll Robertson pupil. It contracts slowly during the effort of accommodation convergence for near objects and remains small for thirty seconds or longer. After the effort to converge is relaxed, it regains its original size only after dilating sluggishly. It is unilateral in 80 per cent of the cases and is usually on the left side. The pupils are unequal, the affected one is frequently somewhat dilated, larger and is usually oval in the horizontal or vertical plane. It varies in size from time to time. When markedly enlarged it cannot be used for close work. It dilates readily, rapidly and completely to the mydriatics and to painful stimuli. It contracts in a similar manner to miotics. The condition is benign and is not rare. It is important only because it is to be differentiated from the Argyll Robertson pupil of syphilis. It holds a position analogous to that of pityriasis rosea in dermatology. In this syndrome, that is, pupilotonia with absent tendon reflexes, there is no evidence of syphilis and there are no signs of organic nervous disease. It is seen more frequently in women and in those of neurotic temperament who have undergone some recent emotional upset. There is a familial tendency and many of these patients exhibit dermographism. There are only two points of similarity between this condition and that of tabes dorsalis: the pupils do not react to light or shade directly or consensually and there is almost invariably an associated loss of the deep tendon reflexes.

Analysis of Various Infant Foods.—O'Donnell studied 1,237 newborn infants given seventeen different complemental foods. A comparison of the weight progress shows a difference among the various series, but after close observation the differ-

ence is so slight that none of the foods administered could be considered far superior to the others in value. The author believes that it matters little which food is given as long as it is carefully controlled. The important factors are the caloric content of the food and the fluid intake of the infant. With properly prescribed complemental feedings, infants show a better weight progress, the infants regain their weight more rapidly, there is little if any inanition fever, little if any dehydration, the initial loss of weight can be decreased, the nursery is quieter and the babies are more contented than with breast milk alone.

Oxyuriasis in Private Nursery School.—In a modern, well-equipped private nursery school in Washington, D. C., Cram and Nolan determined the incidence of infestation with pinworms (Enterobius vermicularis). The pupils (131) consisted of white children from 2 to 9 years of age of both sexes from families of a fairly high social-economic status. The children examined comprised two principal groups—106 who were in the school for varying lengths of time in 1937, some of them continuing in the first half of 1938, and twenty-five who entered in 1938, practically a year after the examinations had begun and control measures of a therapeutic and prophylactic nature had been instituted. None of the twenty-five children were under observation for more than six months. In the group of 106 children examined during the eighteen month period, fifty-eight showed evidence of pinworm infestation at some time during this period. A higher incidence of infestation was found in the boys than in the girls. Distinct from the 106 children who entered the school during 1937 were the twenty-five children who entered the school for the first time in 1938 after control measures were instituted. Of the twenty-five newcomers, seventeen were boys and eight were girls. In this group, two children showed positive results for pinworms, both boys. One of the boys was positive on the first examination, soon after entering the school; the other boy showed negative results on two examinations made during the first month but positive on the third examination made early in the second month. Examinations during the next several months indicated a marked reduction in incidence. The validity of this decline was tested critically by increasing the number of swab examinations; a larger number of swabs was examined in March 1938 than in any other one month, both as to the total number and as to the average number per child. No new cases of pinworm infestation were found during the last five months of the investigation. In addition to the pupils in the school, thirty-four persons associated with the pupils were examined; eight of these persons showed positive results for pinworms. Of these eight cases of oxyuriasis, three were mothers, one was an older brother, one a maid in the home of pupils who gave positive reactions and three were persons associated with the pupils in the school.

Primary Tuberculosis and Respiratory Infection.—Hosen and Miles state that a primary infection, no matter what the age of the person at the time, may heal completely so that the patient loses his cell sensitization to tuberculoprotein, it may become quiescent with an increased specific resistance, it may extend immediately and produce death of the person or it may extend later and produce clinical disease and even death after a state of specific resistance has been established. One of the fortunate effects of a primary infection is the building up of a specific defense immunity. This immunity in tuberculosis, unfortunately, is not a state of absolute protection but a relative protection. It vacillates, increasing and diminishing according to the condition of the patient. Tuberculous infection and tuberculous disease are distinct and different entities and they must be treated apart. The authors have many cases of so-called activity of primary foci, but they have been hesitant to label these cases as due to the effects of tuberculous toxin, for (1) after preventive treatment for active tuberculous infection many patients fail to show any improvement in their symptoms, (2) the symptoms of cough, instability of the nervous system, tiredness, restless sleep, anorexia, sweating, leukocytosis, rapid heart, anemia or rise of temperature are often associated with nontuberculous disease of the respiratory system even in children

with tuberculous infection and (3) the x-ray evidence of tuberculous infection is similar to the x-ray evidence in chronic bronchitis. Thus it is difficult to say whether the exudative process in the hilus is due to tuberculous infection or to nonspecific infection. Consequently they undertook an investigation of 100 tuberculous infected children. The sinuses were studied, for in their experience the large majority of children with chronic sinus infection have a secondary bronchitis. The reverse is not true, for often a bronchitis is present with negative signs in the sinuses. Sixty-six of the 100 tuberculous children showed definite x-ray evidence of chronic sinusitis. Treatment of the sinusitis was instituted in a representative number of these cases with the result that all symptoms of active disease were completely alleviated. This was ample evidence that the presenting symptoms were due not to open foci of tuberculous infection but to a nonspecific sinusitis. A number of these patients had preventive care without any relief. The authors are not prepared to say whether the sinus infection or the tuberculous infection occurred first but emphasize that the presence of sinusitis in a tuberculous infected child will lower the patient's resistance and thus may lead to an early breakdown of the primary complex with a resultant active tuberculosis. Also the presence of sinusitis in noninfected individuals will lower body resistance and may cause a special susceptibility to infection by the tubercle bacilli. Whenever a tuberculous child shows symptoms of any activity, a concomitant sinusitis should be looked for before he is labeled as suffering from an active primary complex.

Cysts of Omentum, Mesentery and Retroperitoneum.—Berger and Rothenberg present an analysis of eighteen cases of cysts of the omentum, mesentery and retroperitoneum operated on from 1915 to 1938. They believe that omental, mesenteric and retroperitoneal cysts should be grouped as one—that is retroperitoneal—since embryologically and pathologically they have a similar origin. Symptoms and signs are acute or chronic. The acute symptoms are often occasioned by hemorrhage into the cyst or rupture of the cystic wall. The chronic symptoms are usually mild, the main complaint being that of a progressively growing abdominal tumor. Albuminuria was observed in nine cases. The exclusion, by x-ray examination, of the gastrointestinal and urinary tracts as the seat of the pathologic changes is helpful in establishing the diagnosis of omental, mesenteric or retroperitoneal cyst. Omental cysts are usually large, thin walled, multiloculated, and contain serosanguineous fluid. They tend to rupture easily, thus causing acute symptoms. Mesenteric cysts are often the size of a grapefruit, are thick walled, do not rupture easily but tend to cause intestinal obstruction. If they arise from the mesentery of the small intestine, they usually contain chylous fluid. Cysts arising from behind the posterior peritoneum grow to huge dimensions, are thin walled, rupture occasionally and most often contain straw-colored or serosanguineous fluid. Microscopically the most common observations are either a cystic wall composed of loose fibrous tissue or a flat endothelial layer surrounded by a fibrous layer of tissue. All eighteen patients recovered following operation. Whenever possible, complete resection should be performed but, if hazardous, then marsupialization or simple incision and drainage of the cyst is sufficient. These cysts show little tendency to recur or to become malignant. Extensive surgical intervention was not necessary, the authors state, since complications did not occur in their patients.

Efficiency of Preoperative Sterilization of Skin.—Novak and Hall found an average of twelve staphylococci and diphtheroids per square centimeter on normally clean skin. Applications of 50 per cent alcohol and 10 per cent acetone solution, a common solvent for antiseptics, destroy 96 per cent of the bacteria on the skin. Only from 2 to 3 per cent more of the cutaneous organisms are killed when any commonly used skin antiseptic is added to this solvent. Tincture of green soap alone is inefficient for sterilizing the skin, killing only 53 per cent of the bacteria on the skin. The authors state that a concentration of 0.07 per cent mercury bichloride and 0.5 per cent tricresol (costing about 5 cents a gallon) in 50 per cent alcohol and 10 per cent acetone solution make an efficient and inexpensive skin antiseptic.

*Clinical Recognition of Pick's Disease: Report of Three Cases. L. Benedek and T. Lehoczky.—p. 104.

Pick's Disease.—Benedek and Lehoczky cite three cases of Pick's disease diagnosed during life, all of which presented peculiar arteriographic and ventriculo-encephalographic features. In two cases confirmatory evidence was obtained by cerebral puncture. The encephalogram showed opercular cysts in one case in the fifth ventricle, in another on both sides. A progressive increase in the size of these cysts was demonstrated by encephalograms taken at intervals of from four to six weeks. Cerebral angiograms showed changes attributable to atrophy. Cerebral puncture demonstrated a severe degeneration of the frontal cells and axons, an activity of the glia and in case 2 incipient senile plaques. On the ventriculogram in case 3 the projection of the frontal horns of the lateral ventricles became enormously bulging, especially on the left side, thus giving the ventricular system a peculiar dumb bell-like or clublike appearance. On the basis of these three cases the authors assert that the clinical syndrome in itself is sufficient for the differential diagnosis of the disease.

*Severe Skin and General Reaction Following Administration of Sulfapyridine and Exposure to Ultraviolet Light. R. Hallam.—p. 559.

Modified Bendien Reaction.—The Bendien technic described by Lowe was closely followed by Price as regards the performance of the test itself in the examination of 427 specimens of blood; the only modification was in the method of estimating the amount of flocculation produced by the action of the vanadic acid standards on the various specimens of serum. Either a nephelometer or a photoelectric absorptiometer was used for all estimations. There was agreement of serologic results with clinical observations in 55.5 per cent of the 427 specimens of blood. Evidence suggests that, the larger the number of cases tested, the nearer to equality becomes the proportion of positive and negative results. In other words, the association of active malignant conditions with a positive result is a matter of chance. Consequent on this, and supported by subsequent history, the test is of no value in the diagnosis, control of treatment or prognosis of the disease. The test has shown itself to be entirely unreliable. There is no quantitative relation between a positive result of the three phase test on a sample of serum and the level of the cholesterol in that particular specimen. Neither was it possible to demonstrate any connection between the serum cholesterol figure and the amount of flocculation in phases B and C of the three phase test.

Recurring Intracardiac Clotting.—Jessiman reports a fatal case of intracardiac clotting precipitated by an attack of acute bronchial asthma and followed by massive embolic infarction of the lung in a young primipara. Evidence was obtained that two years previously the patient survived intracardiac clotting, which also resulted from bronchial asthma. That the patient's previous attacks of acute asthma were of the bronchial type cannot be doubted, as they responded repeatedly to ordinary antiasthmatic remedies, were typically bronchial in appearance and behavior and were relieved by the endocrine readjustment of pregnancy. In the attack of two years ago, which began as acute bronchial asthma, it would appear that the superimposed heart signs and symptoms were due to intracardiac clotting. The heart signs appeared rapidly, the patient all but died within a few hours, the attack was apyrexial, recovery was rapid, and following it there appeared definite and rough valvular murmurs which cleared up with incredible speed. It is probable that the murmurs were due to an organized thrombus either in the right auricle or in the right ventricle—more likely the latter—moored to the chordae tendineae of the tricuspid valve (as found post mortem) and that the rapid disappearance of the murmurs was the result of the rapid organization and absorption of the thrombus. Moreover, the fatal attack started in an exactly similar way, and the postmortem observations gave a positive explanation of the course of events in this final attack. It appears that intracardiac clotting may take place in the absence of endocarditis and may give rise to the signs of a gross valvular lesion. A seriously damaged heart may show no direct physical sign of failure even with the strain of pregnancy and a lengthy labor.

Photosensitization and Sulfapyridine.—Since it does not appear to be generally recognized that a severe cutaneous and general reaction may take place as a sequela to exposure to light during or following the administration of the sulfanilamide group of drugs, Hallam cites such a case. Only a small dose of sulfapyridine was taken by the patient but shortly after an exposure to ultraviolet irradiation a dermatitis, elevation of temperature and raised pulse, that is, a general reaction, took place. Therefore there appear to be grounds for assuming that this man's skin was photosensitized by some chemical reaction following the administration of sulfapyridine and that the exposure to a moderate dose of ultraviolet radiation precipitated the onset of an intense reaction. It is desirable that every prescriber of sulfapyridine should be aware of this potentiality and that every patient be expressly warned of the danger of exposure to strong sunlight or any form of artificial sunlight during the time he is taking the drug.

Lead Poisoning.—Tompsett and Anderson examined the lead content of the blood and excreta in twenty-nine cases of suspected lead poisoning. Eleven of these were finally diagnosed as plumbism. In ten of the cases of poisoning the content of lead in the blood was greater than 100 micrograms per hundred cubic milliliters of blood and varied from 100 to 400 micrograms. The total daily excretion in the urine and feces varied from 0.22 to 2.82 mg. and did not run parallel to the level of lead in the blood. The remaining patient showed a blood lead content of only 75 micrograms but a daily excretion of 1.27 mg. The authors suggest that more than 100 micrograms of lead per hundred cubic milliliters of blood or a total daily excretion of 1 mg. or more indicates lead poisoning.

Sulfapyridine and Pneumococci.—In order to avoid the extra work generally involved in determining the sensitivity of the different pneumococci to sulfapyridine, Maclean and his colleagues adopted a method in which a fixed amount of sulfapyridine was added to blood infected with various dilutions of a pneumococcus culture. This enabled them to obtain an end point with an unknown culture without any preliminary titration. Experiments were made with various concentrations of sulfapyridine in blood, but usually a strength of 1 in 20,000 was used. By this method they have tested strains of thirty types of pneumococci and in the case of certain types a number of different strains were tested. They found that pneumococci vary enormously in their sensitivity to the drug and that this variation is not associated with the type of pneumococcus but with the individual strain. Experiments in mice confirm the results obtained in vitro. It is suggested that whenever possible such a test should be carried out and according to the result obtained forecasts can be made as to the result likely to be obtained with sulfapyridine treatment. If the infecting organism is sensitive, simple treatment with the drug will probably be effective; if it is only moderately sensitive it is likely that some increase in immunity will be necessary in addition to sulfapyridine treatment; but if the organism is insensitive to sulfapyridine in concentrations which can be attained in the human body there is no justification for embarking on a course of such treatment, which cannot do good and may have serious toxic effects. A single dose of pneumococcus vaccine given to mice or rabbits profoundly affects the course of an experimental infection in these animals when treated with sulfapyridine, indicating the combined use of vaccines and sulfapyridine in all cases of pneumonia in man. Experiments are cited which show that pneumococci can, in an infected animal treated with sulfapyridine, readily establish a tolerance or fastness to the drug. This makes it essential that the initial doses should be large, and also—as sulfapyridine merely interferes with the growth of the bacteria and the body has to do the actual killing—it is essential that the immunity should be raised to as high a degree as possible by any means, active or passive, specific or nonspecific, so that the destruction of the bacteria may be complete before tolerance to the drug has been established.

Surgical Revascularization of the Heart.—O'Shaughnessy and his associates summarize the experimental evidence in favor of surgical revascularization of the heart and present the results which have accumulated during the last three years. Microscopic and injection studies show that vascular connections will develop between the vessels of the myocardium and extracardiac vessels (1) when cardiopericardial adhesions are produced with aleuronat, (2) when a pedicled omental graft is introduced into the pericardial sac and adhesion between the omentum and the heart is stimulated with aleuronat and (3) when the omentum is grafted to the outer surface of the pericardium after the production of cardiopericardial adhesions. Collateral communication will develop between the pulmonary and coronary circulations if a lobe of the lung is grafted to the myocardium.

Herpes Simplex.—Burnet and Lush studied the content of human serums in antibodies against herpes virus. The results bring herpes simplex infections much more closely into line with other virus diseases. The position seems to be that primary herpes is an infective disease spread by droplet infection or by salivary contamination, particularly in the age period from 1 to 3 years. The initial lesion is a vesicular stomatitis, often with fever and not uncommonly associated with secondary bacterial infection. In all probability, once infection has occurred in infancy the virus remains present in the body throughout life. In no other way is it possible to account for the fact that, irrespective of the age of the subject, if antibody is present at all it is present in high titer. The site of the persisting infection is still unknown. The two most important possibilities are that the virus remains dormant (1) in the nervous system, with the gasserian ganglion as the most probable site in relation to labial herpes or (2) in the epithelial cells of the buccal cavity, which is the locus favored by Levaditi and his collaborators (1922). The virus is not demonstrable by inoculation methods in the gasserian ganglions of persons with high titer antibody in their serum. Herpes antibody was much more common in serums from hospital patients than in those from a group of fifteen university graduates. There is no relation between susceptibility to clinical poliomyelitis and absence of herpes antibody. Herpes virus could not be demonstrated at necropsy in the gasserian ganglion of persons with high titer herpes antibody. Aphthous stomatitis in infancy is the common manifestation of primary infection with herpes virus.

Hemoptysis and Lung Infiltration Caused by Avitaminosis.—While treating a number of patients with citrin for hemorrhagic diathesis, Jersild encountered a patient whose main symptoms were a pulmonary disorder with hemoptysis and x-ray evidence of infiltration in the lungs. Under this treatment the tendency to hemorrhage and the pulmonary symptoms receded. Presumably the author believes that the only explanation of this case is hemorrhage in the lung tissue with hemoptysis. He previously reported (1938) a case of hemorrhagic diathesis (Schönlein-Henoch purpura) in which there were hemoptysis and x-ray changes in the right lung. In spite of careful examination at various tuberculosis dispensaries no pulmonary tuberculosis was found in this patient either. He states that the present case emphasizes the advisability of always testing the capillary resistance in hemoptysis in which no causal organism can be found. It would be of interest to investigate whether some of the hemoptyses of tuberculous patients are not the result of a deficiency of vitamin P.

Mammary Cancer During Pregnancy and After Delivery.—Verne and his associates report the clinical history of a woman, aged 35, who observed the development of a nodule in the upper portion of her right breast. The nodule was excised and diagnosed as an adenoma, but the microscopic examination revealed that it was an epithelioma. Roentgen therapy was instituted and it counteracted the subcicatricial induration. An examination several months later revealed nothing abnormal; the patient was satisfied and declined another surgical operation. Several months later she became pregnant, and when the pregnancy had advanced to about four and one half months she consulted an obstetrician about the appearance of an abnormal mass in the region of the surgical scar on her right breast. This nodosity had reappeared toward the end of the third month of the pregnancy. The mass increased in size, but resumption of the roentgen therapy was not advised in the course of the pregnancy. At the end of the pregnancy the size of the tumor had nearly doubled. The delivery was normal, but when eighteen days later the woman entered the cancer institute for renewed roentgen treatment of the mammary tumor it was found that the tumor had practically doubled since the day following the delivery. Moreover, in spite of intense roentgen therapy the neoplasm grew further and the woman was urged to undergo an operation, to which she consented. The authors describe and discuss the histologic aspects of the surgical specimen and direct attention to possible connections between tumor growth on the one hand and pregnancy and delivery on the other.

Inhibiting Action of Androgen on Induced Cancers.—Flaks and Ber say that in previous investigations they found that if large doses of androgen are injected into mice that are treated with methylcholanthrene the androgen acts as a prophylactic against this cancerigenic substance. In the work reported here they repeated their tests on mice with some modifications, using methylcholanthrene and benzypyrine as cancerigenic substances. They describe tests on several groups of animals and record the results in tables. It was found that the injection of large doses of testosterone propionate before and after the treatment with benzypyrine exerts an inhibiting action on the formation of cancers of the skin. However, this prophylactic effect persists for only a certain time after the injections. In the group of mice having received the prophylactic treatment with the androgen, cancers appeared two months later than in the control animals; to be sure, they were also fewer in number than was the case in the controls.

*Dangers in Introduction of Radioactive Substances into Organism. S. Laborde.—p. 393.
Asepsis of Operating Rooms. F. Masmonteil.—p. 394.

Dangers in Introduction of Radioactive Substances.—Laborde points out that the risks involved in the introduction of radioactive substances into the organism are of various forms, but in this report he disregards the affinity for the osseous system as well as for the reticulo-endothelial system and gives his attention to the cutaneous complications. He maintains that such complications are more numerous than the literature on the subject indicates. The majority are provoked by the injection of the salts of mesothorium and are ascribed to the local retention of the substance, which has an extremely long life. It has been said that thorium X is less dangerous by reason of its much shorter life. However, the author maintains that it is an error to believe that thorium X does not provoke harmful biologic effects. He relates the clinical history of a woman who in 1927, on account of vertebral rheumatism, was given a series of injections of thorium X. The injections were given into the gluteal region at weekly intervals and the doses administered were 50, 100, 150, 200, 250 and 300 micrograms; that is, about 1 mg. of active substance. Although this dose is rather high, it is frequently administered in painful disorders. In 1937, that is, ten years after the injections, a deep-seated induration, which had persisted since the end of the treatment, became red and sensitive and opened spontaneously to discharge a white material. Cicatrization was effected gradually, but a fistula remained which still persisted in March 1938, when the author examined the woman for the first time. Roentgenoscopy disclosed a considerable amount of opaque substance in the gluteal region. The patient was pale and complained of extreme fatigue. Examination of the blood disclosed a mild anemia but a considerable leukopenia. Because it was feared that the cutaneous lesion might increase and perhaps become malignant, it was decided to extirpate the damaged skin and a considerable portion of the adipose tissue, which inclosed a hard, white substance. The removed tissue was subjected to chemical, spectrographic and microscopic examination and to radioactive analysis. These studies demonstrated that the soluble radioactive salts, chosen because of their diffusion in the organism and of their rapid elimination, give only an illusory security; the persistence of a certain quantity of the product, no matter how small, suffices to elicit tissular disorders. The anemia observed in the reported case can be explained not only by the probable fixation of radioactive salts in the reticulo-endothelial system but also by the constant liberation (for a period of ten years) of thoron and radon. The radioactive analysis disclosed that the injected product was not pure thorium X but contained mesothorium and radium. It is difficult to obtain a pure preparation of thorium X and the author thinks that the inequality of the results and the fact that the complications vary is due to the fact that it is difficult to obtain uniform products.

Brucellosis in Human Beings.—Janbon and Caderas de Kerleau report what they believe to be the first clinically authenticated case of human miscarriage due to Brucella melitensis. The patient was a woman aged 34, employed in a slaughterhouse, who had had nine previous pregnancies and seven healthy children living. She was admitted to the Pasteur clinic April 5 and suffered a miscarriage April 26 in the third month of her pregnancy. Analysis revealed Brucella melitensis in the blood of the mother and in the viscera, heart blood and stomach contents of the fetus. It is thus proved that Brucella melitensis is capable of inducing miscarriage in human beings. Previous reports of miscarriages due to Brucella turned out to have been caused by Brucella abortus.

Alkaloids of Phenanthrenic Group: Methylization of Nucleus of Morphine; Action on Biliary Secretion. G. Baltacéano and C. Vasiliu.—p. 123.

Ureagenetic Function of Liver in Diabetes Mellitus.—After pointing out that diabetes mellitus occurs in several forms, Wassilevsky says that, besides the pancreas, the liver plays an important part in the pathogenesis of diabetes mellitus. He cites investigators who studied hepatic involvement in patients with diabetes mellitus and also mentions various tests that have been devised to study the hepatic functions, particularly the urea-

genetic function, and then he describes his own studies on this function. He withdraws a specimen of blood from the cubital vein of the fasting patient and determines the ammonia content of the blood. Then, without removing the needle from the vein, he injects a solution of aminoacetic acid and again takes blood specimens after intervals of fifteen, twenty, forty-five and sixty minutes. In these specimens he determines the urea and the ammonia contents. He describes his experiences with this test and stresses the following characteristics: (1) its absolute specificity with regard to the liver; (2) the existence of close physiologic ties between the ureagenetic reaction and the activity of the hepatic parenchyma; (3) the possibility to make incontestable deductions from the observations on the venous blood; (4) the sufficient stability of the urea as an indicator in the functional test, and (5) the extreme simplicity of the test. In the mild cases of diabetes the ureagenetic reaction is completely preserved, although in some cases it is slightly retarded. In the cases of pure diabetes there is a complete dependence between the condition of the patient, the course of his diabetic disorder and the ureagenetic reaction; that is, as the general condition of the patient improves, the urea content (after its administration) rises, whereas as it becomes worse it decreases. In the cases of diabetes that are complicated or accompanied by other diseases, particularly those of a neurologic nature, a considerable ureagenesis is observed. The explanation of this phenomenon requires intricate studies because of the involvement of the sympathetic nervous system. The employment of the aforementioned test in the clinical study of diabetes will aid in the understanding of the pathogenesis of each individual case and will throw light especially on the role of the liver in the pathogenesis, and thus it will aid in selecting the best method of treatment.

Modern Conceptions on Pathogenesis and Treatment of So-Called Hypertrophy of Prostate. A. Bergamini.—p. 319.
*Changes and Antigenic Power of Cerebrospinal Fluid in Subacute Venereal Lymphogranuloma. C. Pisacane and R. Lopresti.—p. 332.

Cerebrospinal Fluid in Venereal Lymphogranuloma.—Pisacane and Lopresti examined the cerebrospinal fluid of eight patients suffering from subacute forms of venereal lymphogranuloma. The investigations consisted in making morphologic, serologic and chemical examinations of the fluid and in using the fluid as an antigen in performing the Frei test in another group of patients who were suffering from the disease. Two patients in the group had had sufficient treatment and were considered as recovered. The cerebrospinal fluid of these two patients was normal. The Frei tests which were made with the fluid of these patients gave constantly negative results. The cerebrospinal fluid of the remaining six patients was changed. There was hyperalbuminosis in six cases, lymphocytosis in five and positive results of the Nonne and Pandy test in three and of the flocculation mastic colloidal test in all six. The colloidal response was of the syphilitic paralytic and mixed types in two cases for each type. The Frei test was done in several patients who were suffering from the disease with the cerebrospinal fluid of every one of the patients but one, who had syphilis. The test gave typical strong positive results in all cases in which the fluid of one of three patients was used and negative results when the cerebrospinal fluid used was from either of the other two patients in the group. The different response of fluids which had the same alterations showed that the fluid does not produce good antigens in all cases. The same happens when the pus of poradenitic ganglions is used as an antigen. Therefore the author concludes that the virus of venereal lymphogranuloma has a special affinity for the nervous tissues and that the disease is organic general rather than local.

*Testicular Hormone in Hypertrophy of Prostate. P. Bruni.—p. 8.
Fracture of Zygoma Cured by Direct Skeletal Traction with Screw. C. Giorgi.—p. 34.

Androgen in Hypertrophy of Prostate.—Bruni discusses the role of endocrine disorders in the pathogenesis of hypertrophy of the prostate as well as the therapeutic value of androgenic substances. The author resorted to the androgen treatment in a group of fifteen patients who were placed in three different groups according to the evolutional phase (early, chronic and subacute) of the condition. All the patients had intramuscular injections of androgen (synthetic testosterone propionate in doses of from 0.005 to 0.02 Gm. for each injection up to a total dose of from 0.07 to 0.235 Gm. The injections were administered every other day. Patients in whom the disease had lasted for less than one year and had only a moderate residue of urine had the androgen treatment alone, whereas those who were suffering from the chronic and subacute forms of the condition had a combined androgen and local treatment (catheterism and vesical lavages). The treatment induced rapid improvement up to complete disappearance of the subjective symptoms in patients in the early phase of the disease. The amount of residual urine was rapidly reduced. Azotemia and the results of the phenolsulfonphthalein test became normal and the general condition of the patients improved. The size of the adenoma did not change. The satisfactory results have lasted up to the present (four months after discontinuation of the treatment, with the exception that the residual urine slightly increased, never reaching, however, the figures that existed before administration of the treatment). In the second and third groups (those in whom the disease had lasted for more than one year and had considerable retention of urine) the results were of about the same order but much less satisfactory than those of the first group. The author therefore concludes that androgen administered to man is harmless. The general condition of the patients is improved by the treatment, which however does not modify the size of the adenoma. The treatment arrests the development of hypertrophy when it is administered early in the evolution of the disease but does not cure hypertrophy if it is already established. The treatment is indicated early in the development of the disease and as a palliative agent in nonoperable cases, when the operation is refused, in the preparation of the patients for a proper surgical operation and in the prevention of recurrences, after endoscopic resection.

Failures in Treatment of Melanoma.—On the basis of eight cases of melanoma, Lertas analyzes the results of the various methods of treatment of this disease and the reasons for failures. The primary tumor may be so small as to escape observation and the clinical symptoms may be due to a metastasis. Serum diagnosis of a malignant condition is not dependable. Neither the clinical picture nor the histologic character of the tumor permits predicting the possible course. The advocates of operative intervention maintain that the operation is capable of radically removing the original lesion and of obtaining at least a temporary cure. Microscopic examination, however, usually demonstrates that the malignant process is deeper and wider than is perceived by the unaided eye. Microscopic study in one of the author's cases revealed the existence of an isolated metastatic tumor not far from the original growth. The analysis of the results of surgical intervention revealed that, while the majority of the cases metastasize early, there are cases with a slow course surviving decades. The results obtained with melanocarcinomas are not better than those obtained with melanosarcomas. Local recurrence is rather rare for both forms. Lymph node recurrence after removal is seen exclusively in cases of melanocarcinoma. The melanocarcinomas are less refractive to irradiation than the sarcomas, giving cures of from three to five years with irradiation, whereas of the seven cases of melanosarcoma treated by irradiation, metastases and death occurred in six. High voltage roentgen therapy appears at times to act as an activator of the growth whether applied as an independent therapeutic measure or following operative removal. The opponents of operative intervention base their argument not so much on the bad postoperative results as on the fact that many melanomas, when untreated, remain station-

ary for a long time. Adherents of surgical intervention point to the removal of the original tumor and some prolongation of life; adherents of roentgen and radium irradiation report that most of the patients obtained from two to three year cures. The author concludes that the failures of the various therapeutic measures depend not so much on the kind of therapy as on the individual character of the tumor. Neither the clinical picture nor the histologic appearance of the melanoma furnishes definite information as to its malignancy or possibility of metastasis. Metastases occur as a rule but not necessarily in every case. The author does not subscribe to the opinion that every form of treatment, particularly surgical, acts as a stimulus for the formation of metastases.

Roentgen Sarcoma.—Deuticke reports three cases of sarcoma apparently developing as the result of excessive irradiation with roentgen rays and radium. One case developed ten years after massive irradiation of a surgically removed dural endothelioma, one after excessive irradiation of a lupus vulgaris lesion, and one sixteen years after intensive radium treatment of a skin damaged by roentgen therapy for lupus. From the study of the literature and of his own cases the author concludes that tuberculosis per se does not give rise to sarcoma. Where sarcoma developed in a tuberculous lesion the latter was almost invariably subjected to excessive irradiation. The incidence of sarcoma developing in a previously tuberculous tissue which was irradiated as contrasted with sarcoma developing in tuberculous tissue that was not irradiated is as 45 : 10. The relationship of irradiation sarcoma on a tuberculous basis to irradiation sarcoma without a tuberculous basis is as 45 : 11. The combination of tuberculosis and radiation seems to favor the development of sarcoma. The fact that sarcoma appears long after the original tuberculous lesion has healed, as well as the fact that tuberculous lesions are no longer found in the vicinity of the tumor, suggests that it is the prolonged irritation of the skin that is the contributing factor rather than the specific effect of tuberculosis. Sarcoma may develop in an unspecific granulomatous tissue or from an ulcer. Chronic lesions other than tuberculosis may lead to development of a sarcoma. In all these cases, however, sarcoma is a late result of irradiation. The latent period varies from five to twenty years. The sarcomatous tumors are malignant and have a bad prognosis. Histologically they are spindle-cell sarcomas, fibrosarcomas or polymorphonuclear cell sarcomas frequently with a myxomatous transformation. The rare occurrence of the lesion does not constitute an argument against radiation therapy in cutaneous tuberculosis; however, it speaks for the necessity of observing certain precautions.

Action of Dihydrotachysterol.—Jacobi and Tigges were able to observe the action of dihydrotachysterol (A. T. 10) in eight patients with various disorders, some of which were accompanied by hypocalcemia. In a patient in whom tetany and hypocalcemia developed following the surgical removal of an exophthalmic goiter, the symptoms of tetany and of hypocalcemia could be permanently counteracted (observation for two and one half years) by treatment with dihydrotachysterol (from 75 to 180 drops) per month. In a case of sprue with severe hypocalcemia but without symptoms of tetany it was possible to normalize the calcium content with relatively small doses of dihydrotachysterol. However, in a patient with excretory pancreatic insufficiency, colitis and megacolon, in whom signs of tetany and hypocalcemia existed simultaneously, even large doses of dihydrotachysterol did not influence the symptoms of tetany. The authors suggest that a defective resorption might be responsible for this failure. In a case of idiopathic tetany with normal calcium content, which had persisted for fourteen years, small doses of dihydrotachysterol made the signs of tetany disappear, while the calcium content remained unchanged. In a patient with idiopathic tetany and hypocalcemia, relatively small doses of dihydrotachysterol were sufficient to counteract the symptoms of tetany and normalize the calcium content. Hypocalcemia in the absence of tetany, in a child with nephrosis, did not yield to comparatively large doses of dihydrotachysterol. An attempt to counteract the symptoms of osteitis fibrosa cystica by medication with dihydrotachysterol was unsuccessful; the normal calcium content was not increased even by large doses. In a woman who had tolerated unusually large doses for a period of two years without signs of intoxication and without increase in the calcium content, the medication with dihydrotachysterol was discontinued without clinical results and without influence on the calcium content. The authors conclude from these observations that contrary to the generally accepted opinion hypocalcemia is not necessarily influenced by dihydrotachysterol. Tetany and hypocalcemia may develop independently and may also react independently to dihydrotachysterol. Not all cases of hypocalcemia respond to dihydrotachysterol, and a normal calcium content remains uninfluenced even by large doses of this preparation.

Short Wave Therapy in Pulmonary Empyema.—Dieker reports the results of short wave treatment in thirty-two unselected cases of empyema of the lung. Five of the thirty-two patients are excluded from final consideration because short wave treatment was employed as the last desperate resort and did not exceed four treatments. Of the remaining twenty-seven, nineteen recovered, three improved, two had to be operated on and recovered, two died and one was still under treatment. The conjectured duration of illness before treatment ranged from five to 110 days; the number of treatments given, exclusive of the five patients who died, from twenty-five to ninety; the duration of illness after the treatment lasted from thirty-four to 197 days. Many of these patients were extremely ill, creating doubt as to whether surgery ought not to be applied. Some patients were past surgical help, but the short wave treatments were so favorable that surgical intervention was no longer considered. Most of the patients felt better after the first treatment and showed progressive increase of appetite and weight and decrease of fever and fetid sputum. Simultaneous pleural empyema rendered short wave treatment of empyema of the lung more difficult. The author used the apparatus of Siemens with a 6 meter wavelength and, preferably, the glass electrodes indicated by Schliephake. On patients who could be treated only in bed, rubber electrodes were used, together with layers of perforated felt pads. Daily treatments lasting from five to fifteen or twenty minutes were administered. The determining factor for release was the actual condition of the lung as revealed by roentgenograms. Long-continued treatments caused no injury. The age of the patients (from 18 to 65) was no obstacle to the treatment; neither was the size or site of the empyema. Empyemas larger than a man's fist were successfully treated. Multiple and bilateral empyemas, those of various etiology (except when secondary to bronchiectasis) were successfully treated. Defective delimitation of the empyema, transition into gangrene, pyrexia or the patient's general condition were not allowed to delay treatment. The author concludes that short wave therapy in pulmonary empyema is the least violent of all treatments and, with proper selection of clinical material,

promises better results. It can be applied to empyemas of any size or site, to multiple and bilateral empyemas, to empyemas no matter what their etiology, to empyemas that show transition to gangrene, to patients with pyrexia, defective circulation and generally poor conditions and to cases of pleural adhesion of recent origin with promise of improvement and recovery, if treatments are continued for a long time. Treatments, the author says, should not be delayed until delimitation of the empyema has formed but begun as early as possible and be continued until the last vestige of infection has disappeared. Simultaneous pleural empyema makes short wave therapy more difficult and should be previously drained (combined treatment). The author's results are amply confirmed by the compilation of the results obtained by others through short wave therapy. Of 106 patients, eighty-eight recovered, seven improved and eleven died. Statistics for purely conservative treatment of empyema of the lung (hospital, medicines, no short waves) show a mortality rate as high as 75 per cent. The more favorable mortality rate in surgical operations still shows the high average of from 16 to 34 per cent in the experience of experts in surgery of the thorax and is higher in the practice of surgeons who are not chest specialists.

*Pneumoroentgenography of Kidney. B. Bibus.—p. 256.

Pneumoroentgenography of Kidney.—Bibus shows that, although it is generally possible to diagnose renal disorders by means of cystoscopy or by ascending or descending pyelography, there are nevertheless cases in which it is either impossible to employ these methods or they do not produce a satisfactory result. This is the case especially when the pathologic process spreads over the convexity of the kidney and does not influence the hollow spaces. This gap in the methods of urologic examination was filled by Rosenstein, who introduced pneumoroentgenography. After oxygen has been introduced into the retroperitoneal space, the surface of the kidney becomes visible in the roentgenogram. Pneumoroentgenography is especially helpful in tumors of the kidney. The anteroposterior exposure should be followed always by a lateral one, so as not to overlook tumors on the anterior and posterior surfaces of the kidney. In many instances it is advisable to combine the pneumoroentgenography with a retrogressive pyelography. Occasionally the benign malignant character of a tumor may be deduced from the pneumoroentgenogram. A sharp, smooth outline suggests a benign tumor, perhaps a cyst or an adenoma. A humpy or an indistinct contour indicates the possibility of a malignant growth. The second group of renal disorders in which pneumoroentgenography is indicated are the renal deformities, such as hypoplasia, horseshoe kidney and cystic kidney. In acquired changes in the position of the kidney, for instance in nephroptosis or floating kidney, pneumoroentgenography is likewise helpful. It can be employed in the visualization of extrarenal processes, especially in pathologic processes of the adrenals. The author advises against pneumoroentgenography in the large group of inflammatory diseases of the kidney, not only because it has become superfluous since the introduction of intravenous pyelography but also because it may lead to dissemination of the infection. Perinephric adhesions, however, are an exception, for reports in the literature indicate that in these cases the method is without danger and provides valuable information. The author emphasizes that he never introduces more than 400 cc. of oxygen and that with this quantity he obtains clear pictures. Finally he discusses the dangers of the method. He thinks that mild complications, such as emphysema of the subcutaneous tissue, involve no great danger. Injuries of the diaphragm and of the pleura are more unpleasant than dangerous, because when the characteristic symptoms appear the insufflation can be interrupted, before damage has been done. Oxygen embolism, however, should not be underestimated; although it rarely causes fatalities, it may lead to severe collapse. The author concludes that, although the method is not as dangerous as has been asserted by some, it nevertheless involves a certain risk and should be employed only in specially selected cases and after other methods have failed. The only method with which pneumoroentgenography might be in competition is exploratory exposure of the kidney; however, the latter intervention probably involves a greater risk and pneumoroentgenography might therefore be preferred to it.

Ovarian Epithelium After Treatment with Tar and Gonadotropic Substance.—Katz describes microscopic observations on the ovaries and the uterus of white mice, some of which were made on senile animals and some in the course of prolonged treatment with gonadotropic substance and also with the combination of gonadotropic substance and tar. Summarizing his observations, he says that in senile animals the ovarian epithelium is transformed into an erect cylindric epithelium. The same change can be produced by prolonged treatment with gonadotropic substance. However, the author gained the impression that whereas in senile mice the transformation of the epithelium takes place only after the ovarian function has become completely extinct, in mice that have been treated with gonadotropic substance the change is observed while the sexual cycle still persists. It is of interest that some regions of the surface epithelium, namely those covering the corpus luteum, do not react to the gonadotropic substance in this manner. From the fact that the same epithelial transformations take place in senility and after treatment with gonadotropic substance, the author concludes that the reaction of gonadotropic substance plays a part in the senile changes. If the treatment with gonadotropic substance is continued for a long time, squamocellular metaplasias may develop in the uterus but not in the ovaries. The combined use of gonadotropic substance and tar produces the same changes in the ovary and uterus as does the exclusive administration of gonadotropic substance; however, squamocellular metaplasias are now observed also in the ovarian epithelium. If painting with tar is used exclusively, metaplasia is observed in the ovaries but not in the uterus. From this it is concluded that the tar contains an ovariotropic substance. The biologic action of this substance indicates that it differs from estrogenic-gonadotropic substance as well as from 1,2 benzpyrine.

Goat's Blood Transfusion in Gastroduodenal Ulcer.—Bagdassarov and his associates made repeated transfusions of the whole goat's blood into eighty-two patients with gastroduodenal ulcerative disease. From 3 to 12 cc. of the blood (on an average from 3 to 5 cc.) was introduced first at intervals of from two to four days and later at intervals of from five to seven days. A follow-up of thirty-eight cases for periods of from one and one half to two and one half years demonstrated a permanent cure in eighteen, an improvement in thirteen and recurrences with periodic invalidism in seven. Healing by scar formation was demonstrated in a number of cases of roentgen-

ography. The reactions following the transfusion present three phases: In the first phase, in which the duration is from fifteen to twenty-five minutes, there are noted dyspnea, cough, hyperemia of the face, backache and acute exacerbation of the local pain. The second phase sets in from one and one half to four hours after the transfusion and lasts from fifteen to eighteen hours. It is characterized by chills and high fever. The third phase makes its appearance in the form of hives or herpes several days later. The more severe reactions follow the second infusion. In most of the cases there were mild reactions; 8 per cent exhibited severe shock, at times with vomiting and pain and a sense of constriction in the region of the heart. Among atypical reactions were observed two instances of Quincke's edema lasting seven and twenty-two hours each. One patient developed albuminuria and hematuria. All the patients exhibited a transient leukopenia. In cases of shock reaction the phenomenon of fibrinolysis or liquefaction of the blood clot, as well as the hemophilic phenomenon or retarded clotting, was noted. Alterations in the blood albumin present two phases. In the first there is a diminution of the labile coarsely dispersible fractions, in the second a tendency to the increase in the more stable, finely dispersible fractions. Analysis of the biochemical reactions suggests that the posttransfusion reaction is of the nature of hemoclastic shock in the sense of Widal, resulting from profound alteration in the electrocolloidal balance attending on the interaction of the albuminous micelles of the donor and the recipient. The reason for healing and scar formation of ulcers is to be found in the stimulating effect of colloidoclasis with formation of products of breaking down of the albumin by the intracellular ferments. Nephritis, active tuberculosis, hypertension, febrile states, bronchial asthma, heart lesions and certain allergic states constitute absolute contraindications to the transfusion of heterotransfusion. Among the relative contraindications the authors mention old age, generalized arteriosclerosis and hysteroneurasthenic reactions.

Transplantation of Hypophysis into Midgets.—Bogoraz points out that the failure of the many attempts at transplanting viscera was believed to be due to the necrosis or absorption of the transplant. The question of whether, in a successful attempt, the transplant acted as a substitute for the damaged endocrine gland or merely as an activator of the functions of the remnants of the original gland has not been answered. The author describes his own method of transplanting a hypophysis removed from a cadaver into midgets with a hypoplasia or a lesion of the pituitary. The hypophysis is removed from tall healthy persons between the ages of 15 and 35 years from three to six hours after death from acute trauma. The gland is removed together with the corresponding segments of the two internal carotid arteries. A segment of the brachial artery of the patient is dissected free and is compressed between two clamps. The brachial artery is incised at this point and the transplant is sutured to it. The peripheral end of the internal carotid is thus compressed between the clamps compressing the brachial artery. The incised brachial artery is now sutured to the carotid with fine silk sutures. The peripheral clamp is opened first and blood is permitted to enter the transplanted artery and the hypophysis. The central clamp is next removed, after which the transplant is seen to pulsate and take on a pinkish coloration. The author has performed thirteen transplants with this method in five male and six female subjects. Their statures were between 94.4 and 139 cm., and their ages between 9 and 21 years. The greater number of these exhibited sexual hypoplasia and obesity. The transplants took in all of them and effected an increase in growth of from 2 to 15.6 cm. in the period of observation for from one and one half to twenty-five months. Stimulation of the growth was clearly demonstrated in the cases in which the author had the opportunity of observing the midgets for as long as one and one half years before the operation, during which period they did not grow but three weeks after the operation exhibited an increase in height amounting to several centimeters. This increase in height spoke in favor of the effect of the transplant on the growth. Of the eleven patients, only one attained the size of a man of low stature; the rest, although improved, were still midgets. With the increase in growth there was noted a mild stimulating effect on the sexual organs and the libido.

Hepatic Changes in Exophthalmic Goiter.—Pathologic investigations in sixteen cases of exophthalmic goiter and the result of animal experiments convinced Zeldenrust and van Beek that thyrotoxicosis causes toxic damage of the liver. This impairment manifests itself in a noticeable decrease in the glycogen content and in an atrophy of the hepatic cells, which may result in a considerable decrease in the size of the liver. Moreover, degenerative changes may be seen in the hepatic cells. Occasionally the toxic action is so severe that necrosis of the hepatic tissues results; this may be so extensive that the picture is that of acute yellow atrophy of the liver. In chronic poisoning with thyroxine, in which bacteriotoxic influences could be excluded, the authors twice obtained extensive necrosis of the liver, which corresponded with the initial stage of acute yellow atrophy. Small foci of necrosis were found regularly. In the marginal zones of these experimental necroses, as in the liver of subjects with thyrotoxicosis, a slight inflammatory reaction could be seen. Congestive induration is also frequently observed in the liver of patients with thyrotoxicosis. The irregular distribution of blood in the livers of these patients may be the result of degenerative swelling of the cells and of atrophy. Moreover, cardiac insufficiency often causes irregular blood perfusion of the liver. No conclusive evidence could be found for the assumption that the hepatic changes in thyrotoxicosis are the result of a serous hepatitis.

Spontaneous Perirenal Hematomas.—Kaijser emphasizes that in all cases of perirenal hematomas originating from the kidney in which something is known about the cause of the bleeding there is either reduced coagulation ability of the blood or there are anatomic changes in the small or moderately large vessels of the kidney. Perirenal hemorrhages in cases with infarcts appear almost exclusively in septic infarcts, in which there is the greatest possibility of a direct lesion of the small or moderately large arteries. This, he says, is evidence that the anatomic changes are present and that hemorrhages do not occur by diapedesis. In many cases in which the cause of the bleeding cannot be established, small aneurysms or other changes may have been overlooked; in others the hemorrhage may, though less probably, depend on vasomotor disturbances. Diagnosis is based on the triad of pain in the renal region, increasing fulness in the region and signs of internal hemorrhage in the form of a considerable anemia. The importance of a specific diagnosis of the cause of the hemorrhage is stressed. A personal case and several cases from the literature are cited which show that perirenal hematomas due to septic infarcts usually appear after an acute infection, are accompanied by fever and are so characteristic that they may be considered as a definite entity which can be diagnosed in typical cases.

PSYCHIATRY AND GENERAL PRACTICE

AN ORIENTATION

JOHN D. CAMPBELL, M.D.

NEW YORK

Any specialized branch of medicine which fails to provide for a mutual understanding between itself and other branches will become stifled with its own unpractical theories. Ultimately new ideas are tested at the bedside, and this holds true for psychiatry as well as for other branches. Psychiatry needs help from general physicians, specialists and research workers, and in return it has much to offer. The lack of understanding between psychiatry and the other branches of medicine is due to several factors which will be discussed here. As a general physician who has undertaken the study of neuropsychiatry, I feel that I am in a position to point out the causes for this lack of understanding. Unfortunately there is too much institutional red tape to allow the state hospital psychiatrists to maintain a liaison between their work and those in the active practice of medicine.

Part of the misunderstanding arises from the fact that psychiatry is a new branch, that there are several schools of thought, and that the average physician does not have the time to investigate for himself. The general attitude is well reflected in the words of a capable surgeon of my acquaintance, who said of psychiatry "I have not been able to make up my mind whether there is anything to that stuff or not."

One school stresses behaviorism, another repressed ideas, another dissociation of ideas, another individual psychology or inferiority complexes, another analytic psychology and still another objective psychobiology. Each of these schools has exerted and is now exerting its influence on modern psychiatry. No science was born in a day and each has its history of men, contributions, setbacks and new discoveries. The wise psychiatrist is aware of all these schools of thought and applies them according to the case in hand, just as the internist decides between medicine and surgery in each case of gastric ulcer.

PSYCHIATRIC EDUCATION

The psychiatric slant, insight or approach is knowledge that seems to be born in a few but is learned by most physicians by hard work and study. It gives the physician an advantage which places him above the average. One such physician, a general practitioner without any psychiatric training, recently died in an Eastern city. Almost immediately no less than a half dozen of his patients were seen at a psychiatric clinic. That man, by means of patience, understanding and a self-developed psychiatric insight, was able to keep those patients adjusted. He would have resented being called a psychiatrist, but he certainly had developed a psychiatric approach. Other physicians, without training and without a natural tendency for psychobiology, strive hard in medicine and are experts in the scientific phase of their work but neglectful of what I choose to call the art of practicing medicine. How is this psychiatric point of view to be developed?

The medical student today is being given more adequate courses in psychiatry. The work is begun in the academic schools with general normal psychology and is followed in the medical years with psychobiology and lastly psychiatry. Too many courses of the past plunged the student abruptly into psychiatry with no psychobiologic background. Between the two it seems to me that the latter is more important to the physician than the former. Psychiatry courses teach about the frankly psychotic patients who are usually sent immediately to special institutions. Psychobiology, on the other hand, is the subject that gives one a better understanding of everyday people, neurotic patients and patients on the borderline between normal and abnormal. For those who did not study these illuminating subjects in their medical courses I recommend some of the good works now out on psychobiology. William A. White, G. W. Henry, C. M. Campbell and others have written books that would be a delight to any man in the general practice of medicine. Not only will such knowledge help the physician to understand his patients more completely but he will learn to derive a greater pleasure from his practice. Incidentally, some physicians might also be able to improve on their own personalities.

There should be more cooperative work between medical men in each state and their respective state hospitals. There is an abundance of material there for their psychiatric education. Young men, before graduation, could spend a profitable summer in such an institution as clerk, attendant or nurse. State hospital staffs should arrange annual graduate courses of a few weeks for those who care to widen their medical training. Men who have thus acquired a psychiatric insight could be of help in seeing patients on parole from state hospitals in their part of the state. No physician would find this a waste of time, and his psychoneurotic patients would begin to note in him a new feeling of sympathy and understanding. It has been truthfully stated that a knowledge of psychologic medicine would be the greatest force in the prevention of socialized medicine.

PSYCHONEUROSIS

Today as always one of the most important problems to both the psychiatrist and the general physician is that of psychoneurosis. One does not solve a problem

From the Buffalo State Hospital, Buffalo, N. Y.

by making sarcastic remarks. The physician is rationalizing, says the psychiatrist, when he dismisses a patient by saying "she is just another neurotic." The physician who has been trained in cellular pathology and bacteriology finds it difficult to understand the psychoneurotic patient in the light of this training. He must learn to analyze the neurotic symptom. It is an actual disturbance dependent on changes in three definite and important systems of the human body. I will try to show that the neurotic symptom is a dysfunction, involving to a varying degree the endocrine system, the sympathetic nervous system and the psyche (mind or central nervous system). As an illustration, take an ordinary fear reaction. Through the central nervous system a danger (a fire or a gangster) is perceived; through the sympathetic nervous system the adrenals are stimulated to produce epinephrine, more dextrose is released into the blood and the person is prepared for defense or escape. This is a normal functioning of the three systems mentioned and is one which every one is aware of. Another psyche-sympathetic endocrine reaction, and one which more nearly approaches the neurotic symptom, is that of blushing. Embarrassment, which is outwardly manifested in blushing, is a reaction involving a certain association of ideas in the mind about which the individual is particularly sensitive. As a result of this mental disturbance the sympathetic nervous system is stimulated and, probably with some assistance from the endocrine system, the cutaneous blood vessels are dilated. Blushing is a simple but definite emotional reaction not unlike the neurotic reaction except in its simplicity. Like the neurotic symptom it is instigated by a repressed sensitive thought or idea, and also like the neurotic symptom it is beyond the control of the subject. It is also of concern to the sufferer in some cases, and yet one could not tell him to "forget it." One of my patients, an intelligent person, was able to connect his insomnia and "night sweats" with certain painful and sensitive thoughts which stimulated his abnormally keen sympathetic nervous system.

Such an association of ideas may likewise stimulate the sympathetic system to act on the glands of internal secretion to produce a hyperchlorhydria and thereby produce a typical pain of gastric ulcer. The patient feels the pain; it is a functional but actual symptom and deserves attention. The sufferer cannot be accused of "putting on" any more than one could accuse the blusher of shamming his sympathetic reaction. Some writers have aptly compared the neurotic symptom to a referred pain. Just as the referred epigastric pain is a symptom of appendicitis, so may the neurotic pain be an outward manifestation of a repressed painful thought.

Those who prefer this psychophysiologic explanation of neurotic symptoms will find sufficient evidence to substantiate their views. Wechsler [1] said:

> All the facts thus far accumulated point to a reciprocal relationship between the glands of internal secretion and both the vegetative and cerebrospinal nervous systems. It is not altogether established whether the nervous system controls the internal secretions or the ductless glands primarily influence the nervous system. The latter is relatively older phylogenetically, and its presence can be demonstrated in lower forms before there is any vestige of ductless glands. However, there is an undoubted hormonal as well as neural relation between the two systems. The intimacy of the relationship is attested morphologically, anatomically, physiologically, pharmacologically and clinically. It is a well known fact that psychic impulses, mediated through the nervous system, influence the activity of the glands of internal secretion and may give rise to perverted and diseased function. Intense emotions of rage, terror and anxiety may cause hyperthyroidism or glycosuria.

The frequency with which endocrine disturbance is observed in mental patients must have some significance. It is said that more than one third of the schizophrenic patients show such disorders.[2] Involutional psychosis is beyond doubt closely associated with endocrine changes.

The following case from my general practice illustrates the influence that the endocrine system exerts on mental conditions:

> CASE 1.—W. B., aged 21, was the youngest daughter of a teacher in a small town. She was of a quiet and retiring disposition. She had always shown a tendency to be overweight. Her skin and features were coarse. While taking a nurse's training course away from home she was observed to stare into space, keep to herself and eat food left from patients' trays. Examination revealed a slow pulse, mental depression and a low metabolic rate. Thyroid extract caused the patient to become more animated, show more interest and lose weight. She was advised to stop training. Seven months later she presented herself complaining of overweight. She was observed to be more depressed and retarded than her complaint would justify. But again the patient showed improvement on thyroid extract. At the present time she is adjusting well.

It is difficult to say just what kind of mental reaction this is. Psychoneurosis and reactive depression must be considered. Many hospitals would place her immediately in the schizophrenic group. At any rate the case illustrates the close connection between the endocrine system and the mental dysfunction. Those who see these early mental conditions should view the patient from all angles and as a last resort make a diagnosis of a malignant mental disease.

It is erroneously supposed that the neurotic individual could prevent or forget his symptoms if he only cared to do so. The neurotic symptom is itself a by-product of a sincere attempt to overcome a more serious problem. It is a substitution, a replacement of a formidable difficulty by a simpler one. One cannot accuse the neurotic patient of not trying to overcome his illness. The fact is, he attacks a much more serious, more deeply seated problem and is finally able to effect a compensation, so that when the physician is confronted with a simple neurotic symptom he should visualize the agonizing battle which occurred within that patient before the symptom was evolved. Jastrow [3] said:

> To call them imaginary is a crude and ignorant and, in practice, an unjust misreading of the victim's responsibility. The neurasthenic has to fight for every inch of health and poise and, when he wins, deserves a hero medal, for he is a fighter under the unfairest handicaps that could be imposed; he has the hardest task with the least energies to meet it.

Another reason for impatience with the neurotic individual should be considered: A physician expects his patients to return not with the same story of woe but with a report of improvement. When this report is lacking, visit after visit, he begins to feel inadequate and guilty, and consequently he projects this feeling back on the neurotic patient. This is the cause of the defensive expression "just another neurotic." The phy-

sician need not reproach himself if his neurotic patient does not improve in the same way his other patients do. The neurotic patient is not blaming any one but is only looking for a sympathetic, understanding listener.

Physicians who work on the foregoing principles will soon find themselves dropping the word neurotic from their vocabulary and using instead such phrases as menopausal depression, hypothyroidism, mild involutional melancholia and hyperchlorhydria due to psychogenic factors of unknown origin.

PSYCHOANALYSIS

In the first section of the article the various schools of psychology were mentioned. At this point I wish to discuss one particular school that of "repressed ideas" or psychoanalysis, because it has tended to overshadow its mother subject and led many to believe that it dominates the whole field. Still speaking as a general practitioner with a knowledge of psychiatry, I hope to clear up some of the misunderstanding between psychiatry and other branches of medicine. Unfortunately, some psychiatrists and psychoanalysts consider their work too complicated for the average physician and attempt to place themselves on a pedestal by confusing the subject with useless phraseology. Again I maintain that a specialty cannot be built except on the understanding and cooperation of the man at the bedside. Knowledge of psychoanalysis, like other psychiatric methods, has a place in the hands of the general man, and it is for the psychiatrist to effect an understanding.

Sigmund Freud, anatomist of Vienna, in 1888 watched the neurologist Charcot attempt to cure hysteria by hypnotism. Many of the patients returned with their symptoms converted to another part of the body. Freud saw that the underlying cause of the hysteria was not being cured by Charcot's hypnotism. He also tried hypnotism in the treatment of certain neurotic conditions and, as a result of his experiments, was able to prove that human beings possess an unconscious mind. This fundamental discovery had been recognized by philosophers [4] before the time of Freud, but it had a special significance to the medical man. His subsequent work and contributions were built on a more thorough study of the unconscious mind. He found that it used symbolisms, that it paraded in our sleep as dreams and that it had a great deal to do with the lives of neurotic as well as so-called normal persons. It was while studying the unconscious mind that Freud recognized that sexual strivings play an important part in the life of man and that they begin to show their influence not at puberty but at birth. Incidentally, Freud's words on sex are scanty as opposed to the popular belief that his whole school of thought is based on sex. It is to Krafft-Ebing, Havelock Ellis and others that we are indebted for a thorough study of that phase of man.

Having proved the presence of the unconscious mind, Freud evolved the idea on which psychoanalysis is based, that painful ideas and unacceptable wishes, from early childhood, are repressed into the unconscious mind and later make their appearance transformed into outward manifestations which are called neurotic symptoms. Why some people are able to change these painful ideas comfortably into less painful ones, whereas others cannot be so successful, Freud has not been able to explain. Perhaps endocrine and sympathetic dysfunction may have some bearing on this psychophysiologic mechanism. At least Freud stated that his theory was not incompatible with an organic or physiologic explanation. Unfortunately, we have too many enthusiasts who blindly study the freudian mechanisms without trying to find a physiologic explanation for them. It is said that the patient is suffering from an unconscious death wish against the male parent, or, since there was a homosexual arrest in the psychosexual development of another patient, he became neurotic. Going over the same mechanisms day after day, patient after patient, for the last fifty years has been interesting enough for psychiatrists but has tended to separate their work from the rest of medicine.

Besides, these are not fundamental etiologic explanations. They are true observations, and without Freud's ideas we would still be groping in the dark. But are they primary causes? It is as if one discussed the rose spots of typhoid or the night sweats of tuberculosis in a sense that they were fundamental. I maintain that they are interesting phenomena and bear some relation to the disease, but what are rose spots and night sweats compared to the discoveries of Eberth and Koch?

At the present time there is a tendency to develop a physiologic explanation of the neuroses. Even back in 1921 Kempf [5] attempted a beginning in this direction. He said: "Freud's discovery that the [repressed] wish is the dynamic factor in the personality, as one feels it in himself, did as much for psychology and psychopathology as Darwin's theory of evolution did for biology. The next logical development is to account for the physiological nature and origin of the wish. Most freudians do not try to explain it." Kempf gave as the physiology of the wish (which is the dynamic principle of all behavior) the stimulation and counterstimulation of different segments of the autonomic apparatus. Within the latter he included the endocrine system, all smooth musculature and the sympathetic nervous system. He based his ideas on the experiments of Pavlov, Cannon, Watson and Sherrington as well as on his own clinical observations.

Tendencies today are pointing again toward research in chemistry, physiology and endocrinology for an explanation of the neuroses. A recent book, "The Problem of Mental Disorder," [6] gives a relatively small space to psychologic theories. Neurology, biology, physiology, chemistry, neurocytology, neural integration, nutrition and vitamins are the subjects attracting the attention of workers today. No doubt the profession in general will find in modern psychiatry much that can be used in everyday practice.

As Freud [7] returned to Europe from his one trip to America he expressed the belief that Americans were overlooking the real gist of psychoanalysis. Undoubtedly there was misunderstanding concerning his ideas, and apparently Freud was looking into the future. Certain enthusiasts, some of whom were poorly adjusted themselves, immediately connected psychoanalysis with sex perversion and voodooism, causing the scientific medical man to beware of its influence. Today, however, Freud's teachings are becoming settled to their practical application. Our best analysts recognize and speak of its limitations, but all psychiatrists feel indebted to psychoanalysis not only as a method of treatment but as a school of psychology. It is a psychology which

guides us in our histories, care, treatment and interpretation of patients and their problems. Orthodox psychoanalysis itself is comparable to research in other lines, and as various mental mechanisms are uncovered in the psychologic laboratory the psychiatrist has more with which to work.

For those who do not care to study the unconscious with Freud as their teacher, I recommend the great literary men who were the first psychologists and learn from them indirectly how the unconscious mind directs conscious activities. Follow Becky Sharp with Thackeray or Lord Jim with Conrad for some beautiful psychologic observations. The unconscious death wish was well expressed by Bernard Shaw in the hell scene when Don Juan says "You may remember that on earth—though of course we never confessed it—the death of any one we knew, even those we liked best, was always mingled with a certain satisfaction at being finally done with them." Such lines as Gertrude's in Hamlet "the lady doth protest too much, me thinks" serves to illustrate Shakespeare's intuitive feeling about human behavior.[8]

The general physician will find a study of psychoanalysis to be gratifying to his professional outlook as well as to his everyday enjoyment of life. Psychoanalysis of the family[9] should be of particular interest to the general physician. He is in an ideal position to observe a family over a period of years. The hysterical daughter, though married, still within the shadow of the domineering mother, is an example. The stern grandfather, the sacrificing mother, the neurotic daughter, the drunkard son, the well adjusted cousin—all these parade before the eyes of the family physician. He can watch the little child, as she trudges along to kindergarten, trying to adjust life's problems to the maladjustments of those at the family fireside. And the family physician, who has insight into these important relationships, is in an enviable position to suggest here and there and perhaps save a susceptible child from a miserable life of neuroticism. Knowledge of psychoanalysis can be made a useful ally of every medical man.

As a sailor who does not believe the world is round is obliged to sail his ship, using a round world for his plots and guides, so shall the physician who does not believe in psychoanalysis be obliged to use that school of thought as one of his adjuncts in taking histories, studying patients and their families, as well as in advising treatment.

DEMENTIA PRAECOX

Lastly, I wish to speak of the dementia praecox patient and his relationship with the medical profession. In our medical course we were taught about the well developed case of peritonitis, with boardlike rigidity and shocked facies. But in practice we are not so concerned over such a patient, who is doomed to die anyway, as we are with the early, mild case of localized peritonitis. So it is in psychiatry. The textbook picture of dementia praecox shows a person with a well developed delusion of persecution, hearing voices and receiving messages through a radio carried in his abdominal cavity. But we are told little about the mild cases of dementia praecox, the patient with only one symptom, and that carefully guarded by an evasive personality. The markedly psychotic patient is sent to an institution, but the mild cases are those seen every day by the general physician. The meagerness of psychotic material expressed by some well developed schizophrenic patients is a thing not generally realized. It is said that some paranoid praecox patients are to be recognized as much by what they fail to say as by what they do say. To overlook such a diagnosis might result in serious consequences. The following is a case from my general practice which illustrates the point:

CASE 2.—Mrs. E. C., aged 32, came for antepartum care in the sixth month of her fifth pregnancy. She showed no psychotic symptoms at that time; she was simple in her behavior, but this was discredited because of her lack of education. She always called me by my first name; she had also called her previous physician by his first name. (If this clue had been followed at the time no doubt some delusional idea concerning her physicians could have been uncovered.) The patient's labor was uneventful. One year later the new baby had pneumonia. Hospitalization was not permitted and the baby's progress was unsatisfactory. After the baby's death the mother stated that she had received messages over the radio for the care of the baby. This was the first and only frankly psychotic symptom expressed by the patient. I had difficulty in convincing the husband that his wife was psychotic. A few months later she became disturbed and was committed to a state hospital, where the diagnosis of dementia praecox was made.

The following case is offered as an illustration of what frequently happens to mildly psychotic persons. The records of any state hospital will show that this case is not an exaggeration but rather typical of what occurs when nonpsychiatric internists and surgeons are confronted with mild psychoses.

CASE 3.—C. S., a man aged 25, complained of vomiting attacks of six years' duration. The patient's father had been an epileptic with psychosis and died when the patient was 3 or 4 years old. Our patient was in the eighth grade at 15 when he began to stutter and have difficulties at school. He then quit school and worked at various jobs; he was a clerk in a wholesale drug firm and a laborer in a garage and later played a saxophone in an orchestra. In September 1926, when he was 19, he began to vomit, especially in the presence of other people. He had always been of a quiet, seclusive disposition, and at this time these traits became more pronounced. He lost weight and his hands became "cold and bluish." He was seen by several physicians and given medicine with no relief. The vomiting continued and he frequently withdrew to his own room when there was company in his home. Finally it became an effort for him to eat with his own family, and he would perspire when attempting to do so. A surgeon was consulted, and in January 1927 the patient was operated on for gastric ulcer. A gastro-enterostomy was performed and the patient made an uneventful recovery from the operation. No improvement occurred, but the patient obtained employment, which he was able to keep for about eight months. The vomiting persisted and his condition continued about the same for the next three years. In 1931 he was seen in a city hospital clinic, where a psychiatrist advised him to try living in the country. He lived on a farm practically alone for six months. In February 1932 he returned to the city, reporting to the psychiatrist that there was nothing left for him but suicide. He was committed to a mental institution.

On admission to the Buffalo State Hospital the patient was quiet, shy and seclusive but cooperative. He was depressed; he said that he had been examined by twenty-three doctors and that suicide was apparently the only way out. He stated that he did not have hallucinations but did say that he had been called vile names by his fellow workers, and he had felt that people on the street were talking about him. He requested that he be permitted to eat in his own room but was told to mix with the other patients and attempt to eat with them. He had a feeling of uneasiness when eating in the presence of others and frequently vomited soon after meals. The patient's history and problems were discussed with him in a sympathetic manner. He was told that his vomiting was of nervous origin

8. Jones, Ernest: Essays in Applied Psychoanalysis, London, International Psychoanalytical Press, 1923.
9. Flugel, J. C.: The Psychoanalytic Study of the Family, London, Hogarth Press, 1926. Kempf.[5]

and that he could overcome it by gradually adjusting himself to his environment. On one occasion he requested an interview with the physician and was found to be worrying over masturbation. Other sexual problems were discussed with him, and he seemed much relieved. He liked the hospital and stated that it was the only place where he had found any relief. He exhibited mannerisms and presented a slightly inadequate emotional reaction. Briefly, the patient made a good hospital adjustment. A diagnosis of dementia praecox was made. He has now been in the hospital six years. Whenever parole or discharge is suggested to him he begins to vomit. He is a good worker, pleasant and agreeable, and takes a part in the hospital orchestra.

Several significant points stand out in this case. The underlying personality of this individual was either overlooked or its importance was not recognized by at least a dozen physicians. The definite mental symptoms accompanying his chief complaint were apparently discarded as unimportant. A threat of suicide was necessary before he could obtain sympathetic consideration. A final observation here is the small amount of consultation necessary for this patient to make a fair adjustment.

PELLAGRA OF KENTUCKY MOUNTAIN FOLK

AMBULATORY TREATMENT WITH NICOTINIC ACID

JOHN H. KOOSER, M.D.
HYDEN, KY.
AND
M. A. BLANKENHORN, M.D.
CINCINNATI

Since remarkable results of nicotinic acid treament of acute pellagra have been reported from numerous sources [1] it naturally follows that the same treatment should be tried in recurrent and chronic forms of the disease as seen in an ambulatory clinic. The application of dietary measures, even with the aid of yeast, has not been satisfactory with the ambulatory patient. Now, with an inexpensive and easily administered remedy, so-called control of the disease could be attempted. At the invitation of the Frontier Nursing Service, Inc., of Kentucky and the Health Department of Perry County, the treatment of ambulatory cases among mountain folk was started in April 1938 in a public health clinic. The study and methods of treatment were similar to those used by the University of Cincinnati, under the guidance of Dr. Tom D. Spies, at Birmingham, Ala.[2]

Unlike the clinic treatment recently described from Augusta, Ga.,[3] our method of therapy attempted to fit the dosage to individual cases and to the complaints, and therefore much larger amounts were given.[4]

Perry County lies in the southeastern part of Kentucky and in 1930 had a population of 42,186. Its largest town has a population of 7,061. The chief industry of the town and county is coal mining. The coal miners are, in the main, mountain folk who cling to the traditional diet of syrup, corn meal and fat meat. Combined with this is the fact that they are no longer farmers. They usually have the customary miner's cabin, with a small plot of ground, and go as the coal industry goes. The county population otherwise is rural, of the mountain type. Pellagra has been endemic here for a long time. These circumstances of dietary habit and economic isolation were ideal for therapeutic trials, for neither the patient nor the physician could do anything about changing the diet.

The majority of the patients who attended the clinic were referred by local physicians who were interested in the nicotinic acid study. Others were referred by patients who were receiving treatment. Only those patients who gave evidence of active pellagra were selected for treatment.

The material of the study (from May 15 to Nov. 1, 1938) is summarized in table 1. In the main, table 1 is self explanatory except that two patients were from the same family—mother and daughter. There was an uncommonly large proportion of multiparous women. On the first visit to the clinic a definite history of pellagra was obtained. The course of the present attack was recorded in chronologic sequence. The dietary history included the type and amount of food consumed and the source of the food supply. Associated conditions and diseases that might be contributory also were listed. Further notations were made about the patient's physical status. Subsequent visits, at weekly intervals, included general observations about the patient's course, weight, blood pressure, pulse rate, state of dermal lesions and visible mucous membrane lesions. Neurologic examinations were done as indicated by subjective observations. Tendon and muscle reflexes were elicited as well as proprioception, touch, pain and pressure. Further examinations were done as time and facilities permitted.

"Duration of disease" is given in terms of onset of the first symptoms of the current attack in weeks prior to the first visit. In the majority of cases the onset of the dermal lesions and the onset of the disease coincided. In others, general subjective symptoms or diarrhea began from one to eight weeks prior to the onset of other symptoms.

"Previous attacks" show recurrent and initial attacks, twenty-four and seventeen respectively. One notes previous attacks ranging from one to ten, with a child aged 10 years having its fourth recurrent attack.

Under "associated conditions" are listed miscellaneous data such as nursing mothers (six) and those having menopausal symptoms (seven). Several had hypertension in contrast to the expected normal of hypotension.

Only the pellagra-preventing types of food are tabulated under "diet." This is done with the full realiza-

From the Department of Internal Medicine, University of Cincinnati College of Medicine, and the Frontier Nursing Service, Inc., Wendover, Ky.

The Perry County Health Officers and their staff helped in this work as well as the physicians who sent patients to us. We were aided by Miss Marion Ross, statistician of the Frontier Nursing Service, Inc.

tion of the many discrepancies that exist between food reported consumed and food actually consumed. As a rule, the tendency was to conceal the facts about the scarcity of adequate fresh foods. Local farms are known to be limited in size and fruitfulness, save in a corn crop. Mining income was markedly limited in this particular season (employment only up to three days a week). The food supply came from the general store or the company store. The chief food articles purchased are dry salt bacon, lard, flour and bolted meal, sugar, coffee and beans (pinto and navy).[5] Miners in mining sections are frequently obliged to purchase from the so-called commissary, which is more expensive and offers a restricted supply of fresh foods. Gardens, chickens and cows furnish further supplies. Thirty patients reported gardens of varying sizes, five as having a cow and eleven as keeping chickens. The mining group had fewer supplements of this nature. In general, the consumption of vegetables seemed to be adequate among most of the patients having a limited intake of milk, eggs and meat.

Table 2 relates the clinical story. There seem to be any number of combinations characterizing the onset. The usual story is one with a slowly progressive group of nondescript complaints which frequently are of weeks' duration, increasingly severe, until the appearance of objective signs. In other individuals the onset is occasionally objective. All the items listed are observations and complaints made on the first clinic visit. A patient was listed as having mental symptoms if he was confused or incoherent or had hallucinations or delusions. We think that such symptoms are more frequent than is usually stated.[6] Tachycardia was noted as such after a persistent pulse rate in excess of 100 a minute.

The last three columns list the patients in terms of severity of their disease as acute (eleven), subacute (twenty-two) and chronic (six). Two cases were considered subclinical (36 and 39). Of the eleven acute cases, seven were recurrent. The dermal lesions were the chief factor in this attempted classification because of their preponderance.

The clinical course of the patients varied markedly. Dermal and mucosal lesions responded to treatment in a dramatic manner. New and severe lesions cleared up

TABLE 1.—*Descriptive Data*

more rapidly than old chronic lesions. But despite the inactivation of these lesions, complaints such as itching skin, hot mouth and burning stomach often continued. Most of the patients lost weight for the first two or three weeks. Blood pressure changes were uniform in that they all tended to be lowered. Several were extremely low while others, previously high, approximated normal levels under treatment. In two instances, diarrhea was found to antedate the usual early manifestations from one to three months. Nicotinic acid was not satisfactory in checking the diarrhea of this type of patient, but the presence of the diarrhea did not been our experience that doses of from 150 to 200 mg. a day were adequate, if maintained for two or three weeks, after which time the amount could be decreased until the patient was symptom free. For other individuals the initial dose had to be increased markedly (up to 800 mg.). For still others, further increases in amount of medication were required, the chief index as to dosage being the state of the objective manifestations and the patient's complaints.

The estimation of "results" is given in terms of changes in weight and clinical improvement. Changes in weight are given as gains and losses (first clinic

influence the therapeutic response otherwise. We think that in this circumstance diarrhea was the cause of pellagra and not a necessary part of the disease. Menstrual function was restored in several patients with ensuing pregnancies. The menopausal age group had the most intense subjective reactions. All the patients felt stronger, had less burning, slept better or were less nervous after the first (thirty-one patients), second (six patients) or third week (three patients) of treatment.

Table 3 deals with treatment and results. Nicotinic acid was always given in the form of 50 and 100 mg. tablets. A supply for one week was given, with instructions that the tablets were to be taken at meal time. This method of medication had previously been found to minimize certain reactions to the drug.[2] None of our patients complained of any difficulty in taking the substance. The question of adequate dosage is one on which further study is indicated. In general, it has weight compared with last clinic weight). Improvement is shown as complete, partial or unchanged. Under "complete" are listed twenty-eight patients who are free from objective and subjective signs of pellagra. Under "unchanged" is one patient who was treated for one week only. Under "partial" are listed twelve patients who still have complaints. In analyzing the partial improvement group one finds two complaining of general nervousness, one of itching, one of gastric burning, two of persistent diarrhea, two of weakness, one of faulty memory and one of burning in the extremities. One had a recurrence of skin lesions which responded to increased medication. This group also includes two nursing mothers, three patients in the climacteric period and five patients who had mental symptoms.

Under "notations" are listed miscellaneous items such as complaints which persist, associated conditions and other factors which had clinical significance. It

also includes notations as to early pregnancies, of which there were three, and several instances in which hypertension was greatly reduced.

To assess the results completely requires more detail than can be tabulated, but we are certain that twenty-eight of the forty-one patients were completely relieved of the disease with nicotinic acid and no change in diet. The twelve patients who persisted with complaints are described at greater length and, in the main, loss of weight or insignificant gain is recorded. With one exception, the largest gains in weight occurred among those completely improved.

All of the group remained ambulatory save one (patient 28), who was sent to the Cincinnati General Hospital because of persistent diarrhea, probably due to chronic ulcerative colitis. All of the group can definitely be said to have improved on nicotinic acid alone and to have been cured clinically except for mild subjective complaints and diarrhea, which persisted in two instances (cases 17 and 27) in spite of a gain in weight. In this respect nicotinic acid can be said to cure pellagra so far as the major phases of the disease are concerned. There was one patient who had a relapse while under treatment. This patient (30) perhaps should have had larger doses; because of her mental symptoms we are not sure that she always took her medication.

There was fairly good correlation between gain in weight and other clinical signs of improvement. There was also significant correspondence between the state of nutrition and the result. All of the class who were partially relieved, i. e. persisted with impaired health, were among those described as poorly nourished or only fairly well nourished.

In this we see the disease pellagra well controlled by nicotinic acid but a considerable amount of poor health persisting. It is significant that no person who ate more of his poor diet and gained weight thereby had an exacerbation of pellagra.

CONCLUSIONS

Of forty-one ambulatory pellagrins treated in a clinic with nicotinic acid and without change of diet, twenty-eight were completely cured and remained well; twelve were partially improved, and the condition of one who was inadequately treated was unchanged.

The dosage varied according to complaints and other indications and objective symptoms. The largest average weekly dose was 2.8 Gm. and the smallest 0.24 Gm.

Eight patients showed significant gains in weight (5 or more pounds). Fourteen showed a loss of 1 or more pounds.

Nicotinic acid seems to cure pellagra even when poor diets are continued, but relapses may occur. Nicotinic acid may aid in the restoration of health, but among the pellagrins here described a considerable amount of ill health, such as anemia, underweight, diarrhea and a few subjective symptoms, persisted.

HERPES ZOSTER AND VITAMIN B_1

HERBERT RATTNER, M.D.
AND
HARVEY C. ROLL, M.D.
CHICAGO

Vitamin B_1, because of its antineuritic properties, has been suggested for the treatment of a host of conditions, varying from systemic diseases with neuritic symptoms to diseases of nerve tissues per se. Stevenson [1] tried it in a large group of cases and was very favorably impressed with its efficacy. He treated eighteen cases of sciatica, fourteen of neuritis, mainly of the brachial type, and three cases of general debility with vague and multiple nerve pains. He employed it intramuscularly in doses of 1 or 2 mg., giving an average total dose of 33 mg. In 40 per cent of the cases treated there was cessation of symptoms, in 37 per cent very much improvement and in 23 per cent slight or questionable improvement; and Stevenson concluded that "vitamin B_1 provides a factor often necessary for clearing up efficiently a neuritis, without which the condition would probably remain chronic."

Stern [2] too was no less favorably impressed by his experience with vitamin B_1 in a wider variety of cases. He administered it intraspinally in twenty-eight cases of intractable pain and inflammatory and degenerative diseases of the central nervous system. His series consisted of such conditions as inoperable cancer, von Recklinghausen's disease, multiple sclerosis, duodenal ulcer with pulmonary tuberculosis, Paget's disease, alcoholic neuritis of supra-orbital and sciatic nerves, spondylitis, degeneration of pyramidal tracts, beriberi, pruritus ani and vulvae, and other conditions. Improvement was noted in all of the patients; they felt better and looked better; pain in every case was lessened or abolished; the appetite improved as well as muscular control, speech and gait. The patient with von Recklinghausen's disease responded most favorably.

These and other reports, all in the same optimistic tone, led us to try vitamin B_1 for the pain of herpes zoster. Herpes zoster is generally held to be a ganglionitis produced by a virus. It is likely that there are many etiologic factors in its production, for any type of inflammation of the spinal ganglion may produce a herpetic eruption. It is probable too that the same points emphasized by Wechsler [3] regarding the causes of polyneuritis may be invoked for herpes zoster. Wechsler suggested that in many cases of polyneuritis which have hitherto been regarded as due solely to a specific cause such as alcohol, lead or arsenic (a not infrequent cause of zoster) one may find an additional and perhaps determining factor in avitaminosis. He suggested too that possibly in every case in which there is a deficiency of antineuritic and other vitamins there must be an additional toxin or poison to bring about degenerative changes. Herpes zoster differs from these other neuritides in that the disease is self limited and usually confers an immunity against subsequent attacks; it is an inflammatory disease but its many similarities to conditions which are said to respond favorably to treatment with vitamin B_1 seemed to warrant a therapeutic trial.

We were able to find recorded but two references to herpes having been treated with crystalline thiamin chloride (vitamin B_1 hydrochloride). Nitzulescu and Triandaf,[4] having obtained good results with vitamin B_1 in a case of trigeminal neuralgia, tried it for herpes of the cornea; and for two patients who suffered very severe pain, prompt relief was obtained from the first injection of thiamin chloride, and complete relief after 6 mg. (1,800 units). Neither of these patients had obtained relief from the usual antineuralgic treatment.

Vorhaus [5] treated only cases of postherpetic anesthesia and paresthesia with vitamin B_1 and his results suggested a quicker disappearance of these symptoms than by the usual methods.

For these reasons we tried the use of crystalline thiamin chloride in sixteen cases of herpes zoster. Our cases were from the dermatologic clinics of a large charitable hospital and a medical school. Of twenty-five persons we were able to follow sixteen to the point at which we felt that sufficient amounts of the vitamin had been administered to determine its efficacy.

Crystalline thiamin chloride in doses of 2,000 international units was administered subcutaneously so that there could be no doubt as to cooperation on the part of the patient. The injections were given every second or third day in a group of seven males and nine females. The results with the treatment with thiamin chloride were as follows:

Two children, aged 9 and 13 years, were completely relieved of subjective symptoms after the first injection of 2,000 units. A third child required 4,000 units. The first two children were treated on the third and seventh day of the disease respectively and the third child on the seventh day of the disease, so that one can assume that the treatment did not have a strikingly beneficial effect in these cases, for the disease acted as it usually does in children. One patient, aged 62 years, obtained considerable relief after having received 6,000 units on the fifth day of illness. Another man of 48 years reported only occasional discomfort after 8,000 units (fifth day of illness). There was no relief from the treatment in the remaining eleven cases, including two of severe postherpetic neuralgia.

Reports in the literature had led us to expect prompt beneficial results from the large individual doses and from the average total dose of 5,620 international units which we employed. In the main we were disappointed, however, for the results were neither good nor bad. Several factors may account for the results:

The majority of our patients were not young and age is often a determining factor in herpes zoster, the severity of pain and length of time varying in direct proportion to the age of the individual. Three of our patients were children, the ages ranging from 9 years to 13 years. One was 20 years of age and the remainder, twelve individuals, ranged in age from 40 years to 80 years.

The day of the disease on which the treatment was started varied from the first day in one instance to the sixtieth day in another. This too is a factor which would seem important in any evaluation of results.

The severity of the subjective symptoms also differed considerably. One patient, aged 9 years, complained

The thiamin chloride used in this study was furnished by Abbott Laboratories.

From the Cook County Hospital, and the Department of Dermatology and Syphilology, University of Illinois College of Medicine.

only of itching; another one, aged 42 years, stated that he had "burning, not real pain"; five patients comprising all those 68 years old or over (from 68 to 80) complained of very severe pain, and in two the severe neuralgia persisted long after the herpetic eruption had vanished. In the remaining cases, nine in number, there was moderate to severe pain. In general, however, the group was adequate for test purposes.

CONCLUSION

Our experience with sixteen cases of herpes zoster treated with vitamin B_1 (thiamin chloride) showed that the treatment gave indifferent results. In two cases of postzoster neuralgia in which we had expected and hoped for effective results there were none. Treatment with vitamin B_1 was no more beneficial than with the usual less expensive methods.

MENINGITIS CAUSED BY STREPTOCOCCUS HAEMOLYTICUS

AND TREATED WITH SULFANILAMIDE

JOHN A. TOOMEY, M.D.
AND
E. ROBBINS KIMBALL JR., M.D.
CLEVELAND

GROUP 1, 1935-1936

In 1935 and 1936 eleven patients with meningitis caused by hemolytic streptococci were treated in the Division of Contagious Diseases, City Hospital, Cleveland. Ten of these patients died. Seven other patients with streptococcic meningitis who died during this period are not considered in this report because either the streptococci found were nonhemolytic (two cases) or the organisms were not grown on blood agar and hemolysis had not been demonstrated (five cases).

The ages of these patients ranged from 4 weeks to 51 years; two were adults and nine were children from 4 weeks to 6 years of age. Two patients were under 1 year of age; two were 4, two were 5, three were 6, one was 23 and one was 51 years old. In eight cases the meningitis followed acute otitis media lasting from one to seven days; one case followed cellulitis, one erysipelas of the face and another an abscessed tooth. All the patients were acutely ill and toxic on admission, two being unconscious, two delirious and one in convulsions. Their temperatures ranged between 38.5 and 40.5 C. (101.3 and 104.9 F.). All showed signs of meningeal irritation with a positive Kernig sign and so on. Lumbar punctures were done on admission to the hospital. The spinal fluids contained from 290 to 35,000 cells, predominantly polymorphonuclears. In five cases the cell count was under 800 on admission but increased rapidly to several thousand within twenty-four hours.

All kinds of therapy, such as specific antistreptococcus serums, nonspecific serums, blood transfusions, spinal drainage and drugs, were tried. The only patient who recovered was a boy aged 3½ years who had an abscess of the left forearm which was incised and drained. Blood transfusion was employed and the patient's temperature became normal on the fourth hospital day.

Five of the ten patients died in from one to three days, one in five days and the remaining four in from twelve to twenty-two days after admission to the hospital. In eight cases an autopsy was performed; mastoiditis was found in six.

From 1926 to 1934 inclusive, forty-eight of fifty patients with streptococcic meningitis died.

GROUP 2, 1937-1938

Twelve patients with meningitis caused by hemolytic streptococci were admitted to our divisions during 1937 and 1938. In ten cases cultures of hemolytic streptococci were obtained from the spinal fluid. Although streptococci were found and easily demonstrated in the spinal fluid in two cases, they did not grow on blood agar and therefore hemolysis could not be demonstrated. They probably were hemolytic, however, since the meningitis followed otitis media complicating scarlet fever, from which hemolytic streptococci had been recovered.

Eight cases of meningitis followed otitis media, one sinusitis, one an infected laceration, one cellulitis of the scalp and one septicemia with associated sinusitis.

The condition of the patients on admission and the conditions found on physical examination were essentially similar to those found in group 1.

Three patients were given meningococcus antitoxin before the diagnosis was established. All the other patients as well as these three were given sulfanilamide on the first or at least the second day after admission. The amount of sulfanilamide is calculated as maintenance and initial doses. The initial dose is one half the maintenance dose, which is calculated on the basis of the patient's weight, i. e. 1 grain (0.065 Gm.) per pound (453 Gm.) up to 120 pounds (54.4 Kg.) for the first twenty-four hours, given in divided doses every four hours. On the second and subsequent days the maintenance dose is decreased to one-half grain (0.03 Gm.) per pound and is given in divided doses every four hours. One infant received as much as 2 grains (0.13 Gm.) per pound for two days; another received 530 grains (34 Gm.) orally in twenty-four days. Occasionally the drug was given by hypodermoclysis (0.8 per cent in saline solution). It was difficult enough to give the number of tablets needed and almost impossible to give sodium bicarbonate after each dose of the drug. Only in a few cases was this even attempted. The sulfanilamide tablets were ground and swallowed with water. If the patient was unconscious the tablets were ground, water was added and the suspension was given through a Levine tube. The average length of treatment was six days. The sulfanilamide blood level at the height of treatment ranged from 5 mg. to 11.5 mg. per hundred cubic centimeters; the average was 9.5 mg.

TABLE 1.—*Summary of Both Groups of Cases*

	1935-1936	1937-1938
Number of cases	11	12
Otitis media	8	8

Recoveries	1	10
Deaths	10	2
Autopsies	7	1

X-ray examination showed either acute or chronic inflammation of the mastoid cells in seven patients. Eight mastoidectomies were done on six patients. Four patients were operated on the first day, one of whom was again operated on the fifteenth subsequent day;

From the Department of Pediatrics, Western Reserve University School of Medicine, and the Division of Contagious Diseases, City Hospital.

one patient was operated on the third and another on the fourteenth hospital day. The latter patient had been previously operated on at another hospital. All the patients who were operated on recovered.

In this series two patients died (16⅔ per cent) and ten recovered. All of the latter had normal temperatures within eight days after admission. The number of cells in the spinal fluid was usually nearly normal by that time also. Three patients had relapses and therapy had to be started again. The average stay in the hospital was thirty days. One of the two patients who died had a laceration of the head with subsequent massive infection and a fulminating meningitis, while meningitis developed in the other after a subgaleal abscess. Neither infection was adequately drained.

COMMENT

In the twelve cases of streptococcic meningitis reported in this paper and the majority of those described in the literature of the past few years (ninety

landmarks. Resolution of the middle ear may be much delayed, or a recurrence of signs of a middle ear infection with evidence now of mastoid involvement or an otitic complication may rather abruptly follow a longer or shorter period of latency. Otitic complications run an asymptomatic or atypical course, as pointed out in a number of cases that we have reported.

We would suggest to those who are of the opinion that sulfanilamide should be given from the very onset of otitis media that these patients be carefully observed over an extended period despite an apparent improvement in the ear picture and the absence of symptoms; furthermore, as a therapeutic test we would advise the discontinuance of the drug for a few days during the period of observation to note whether a recrudescence of signs or symptoms of postauricular infection occurs. We have made the latter observation in a number of instances in which the drug had been given for a considerable time.

It is not our purpose in the slightest degree to minimize the remarkable effects of this drug in the conditions previously mentioned. We hope only to convey to those who permit untempered enthusiasm for the indiscriminate use of the drug our experience in the recognition of distortion of known entities by sulfanilamide. Conditions that normally run a self-limited course and have a small percentage of complications are subjected to treatment by a drug whose intrinsic potential danger may be greater than that of the disease.

Our experience shows that sulfanilamide used in the presence of a suppurative focus is not as effectual as when used after the focus has been eradicated. This is especially noted in the reports of various observers in the treatment of meningitis. This form of therapy is ineffective if the original focus is not removed. While sulfanilamide will clear body fluids infected by streptococci, its action is apparently less effective on streptococci located in an active bone lesion.

We have demonstrated that sulfanilamide will only partially control suppurative disease and frequently alters the usual clinical picture and tends to prolong its course if proper surgical measures are not employed.

In summing up our point of view regarding the indications for the use of sulfanilamide, we would say that it is inadvisable to give the drug during the period of observation of a patient for suspected mastoiditis, sinus thrombosis, petrositis and the like because of the risk of masking the clinical picture and thus interfering with the diagnosis and proper surgical indications. In the presence of an impending otitic meningitis from whatever cause, the drug should be given immediately. In a case of otitis media before suppuration has taken place, it may be cautiously given. The patient, however, must be under careful observation for a considerable period following its discontinuance.

The following cases illustrate some of our views regarding the administration of sulfanilamide with particular reference to the question of its masking effect:

REPORT OF CASES

CASE 1.—B. B., aged 7 years, during the course of an infection of the upper respiratory tract, had an influenzal otitis media. Two days later a spontaneous rupture of the drum occurred. The patient's temperature ranged between 100 and 101 F. for a few days and the discharge of the middle ear, thin in character, became quite profuse. Sulfanilamide 40 grains (2.6 Gm.) daily was started one week from the onset of the otitis and was continued for six days. The discharge from the middle ear soon stopped and beginning resolution was noted. The temperature returned to normal and the patient's general condition was excellent. It was decided to discontinue sulfanilamide because of the knowledge of a possible masking effect of the drug. Thirty-six hours after sulfanilamide was stopped the middle ear began to discharge profusely and the discharge was thicker than it had been at any time; the drum now had a "boggy" appearance. Increasing mastoid tenderness was elicited and the patient had spontaneous aural pain. The temperature ranged between 99 and 100 F. When the patient had been observed for forty-eight hours, during which the local manifestations increased in severity, it was decided that a mastoidectomy was indicated. Operation disclosed free pus and granulations with areas of softening throughout an usually large mastoid. Hemolytic streptococci were cultured from the mastoid.

A latent or quiescent period during the administration of the drug is shown by this case, which illustrates the importance of careful observation of patients who are given sulfanilamide during the course of otitis media and the diagnostic value of withdrawal of the drug to determine whether the apparent improvement is only a masking effect of the drug.

CASE 2.—B. S., a boy aged 7 years, complained of bilateral acute otitis media March 11 and was given 80 grains (5.3 Gm.) of sulfanilamide by his family physician. A rash developed and the drug was stopped. Suppuration of the middle ear resolved entirely in two weeks. Four weeks later, that is, six weeks from the onset of the otitis, Dr. Morley T. Smith of New Rochelle was consulted. At this time the patient had a temperature of 102 F. and had but little pain in the ear. On examination Dr. Smith reported that the left drum was bulging with very little discharge from an anterior perforation. Culture of the middle ear discharge following paracentesis disclosed a Pneumococcus type III infection. Two days later he was admitted to the New Rochelle Hospital with a temperature of 103 F. and complaining of hemicranial pain. The mastoid was tender; x-ray examination of the left mastoid showed evidence of a destructive process. In conversation over the telephone Dr. Smith reported to one of us (J. L. M.) the finding of an extremely diseased mastoid with a large perisinal abscess (perforated) and a suppurative sinus thrombophlebitis. The sinus was obliterated; there was no bleeding from the jugular bulb. After consultation three days later Dr. Smith decided to ligate the jugular vein. Following this the temperature returned to normal and the patient experienced an uneventful recovery.

Case 2 illustrates the masking effect of sulfanilamide on the course of mastoiditis which had advanced so that there was present a sinus thrombophlebitis recognized only at operation.

CASE 3.—D. Y., with a history of pain in the left ear followed one week later by a myringotomy, with Streptococcus haemolyticus obtained from the ear, had a thin pulsating discharge which continued for the next three weeks. Hearing was impaired and the nasal sinuses were clear. The patient was given 10 grains (0.65 Gm.) of sulfanilamide every four hours. Twenty-two days after the onset of the infection nystagmus developed to the right and left, more marked to the left. This continued unabated, associated with supra-orbital headache. The middle ear showed evidence of resolution up to the day before operation, at which time the ear drum became full and the middle ear began to discharge. On pressure over the mastoid, the patient complained of slight soreness but no actual pain. The sulfanilamide was stopped.

A left mastoidectomy was performed and there was marked destruction of the mastoid; the dura was covered with fine granulations. The possibility of petrositis was entertained because of nocturnal pain, slight postauricular tenderness, thick discharge, subfebrile course and nystagmus directed to the diseased ear. The patient is now on her way to apparent recovery.

The clinical picture was masked by sulfanilamide, presenting a low temperature and absence of pain, evidence of resolution of the middle ear without signs of

mastoid involvement. Petrositis was the first indication of an otitic complication without apparent postauricular disease.

A great deal more pathologic change was found in the mastoid than was clinically suspected.

In the early stages, postauricular tenderness was marked. Following the administration of sulfanilamide, tenderness was definitely absent although there were now evidences of petrositis.

CASE 4.—T. A., aged 10 years, had scarlet fever followed by acute otitis media for which a myringotomy was performed. The ear drained continuously and profusely. The mastoid was not tender. The patient had been given sulfanilamide for thirty days, about 20 to 30 grains (1.3 to 2 Gm.) a day with no cessation of the aural discharge. For one month there was no headache or postauricular pain.

When first seen, the child's temperature was 99.5 F.; the patient was comfortable. There had been a complaint of a vague temporal headache one day before. There was slight postauricular tenderness and a profuse discharge. The sulfanilamide was stopped and the next day the temperature rose to 102 F. The child became restless and headache became marked. Postauricular tenderness was definitely increased.

A simple mastoidectomy revealed extensive disease everywhere in the mastoid with complete destruction of the zygoma and tip. Culture at operation revealed beta Streptococcus haemolyticus.

Sulfanilamide was given early in this case of acute otitis media. There was a definite progression to coalescent mastoiditis despite the use of the drug and absence of headache, fever and other clinical evidence despite marked destruction of the mastoid.

Twenty-four hours after the discontinuance of sulfanilamide there was a reappearance of fever, headache and postauricular tenderness when the masking effect of the drug was removed.

The ineffectuality of the drug in the presence of a suppurative focus and its capacity to attenuate the course of disease without preventing its progression are shown.

CASE 5.—I. C., a child aged 5 years, white, complained of pain in the left ear two days before admission following cough and fever for ten days. On examination the child was acutely ill. The right ear drum was normal and the left was full, red and covered with hemorrhagic blebs and a thin pulsating discharge. Signs of bronchopneumonia were present. The child was given sulfanilamide with onset of the otitis.

Two days after admission the temperature rose to 105 F., the child became irritable and there were meager clinical signs suggestive of meningeal irritation. Lumbar puncture showed an increase of pressure with cloudy fluid containing 230 cells per cubic centimeter, with 92 per cent polymorphonuclear cells. Subsequently fluid was reported to contain beta Streptococcus haemolyticus, as did the culture from the middle ear. Blood culture was sterile.

The child was given sulfanilamide at four hour intervals day and night, 120 grains (8 Gm.) the first twenty-four hours, then reduced to 90 grains (6 Gm.) a day. The concentration in the blood was kept at from 8 to 10 mg. per hundred cubic centimeters. Fever precipitously subsided and the child was comfortable during the next ten days despite the persistence of meningitis as indicated only by examination of the spinal fluid. Within forty-eight hours after the administration of larger doses of sulfanilamide (90 grains a day), all clinical evidence of meningitis disappeared except for the changes in the spinal fluid. The high cell count continued for a few days and the increased polymorphonuclear count was soon replaced by lymphocytes until the day before the mastoidectomy, when the spinal fluid showed a count of 12 lymphocytes. Culture of the spinal fluid was positive for Streptococcus haemolyticus on only one occasion. A few days later, however, slight but increasing postauricular tenderness was noted with persistence of moderate aural discharge.

Twelve days after admission and ten days after the onset of meningitis, a simple mastoidectomy was performed. Complete destruction of the mastoid without involvement of the dura or lateral sinus was found.

In this case meningitis developed two days after the onset of acute otitis media. It was clinically controlled by massive doses of sulfanilamide; the child remained comfortable and playful, with a temperature of from 100 to 100.5 F. despite the meningeal activity as indicated only by lumbar puncture.

There was a definite alteration in our clinical concept of mastoiditis under sulfanilamide.

CASE 6.—J. L., a woman aged 22, had an infection of the upper respiratory tract two weeks before admission. Four days before admission pain developed in the left ear, followed by a myringotomy one day later. For two days before admission she had been dizzy; the type of vertigo was not carefully described. Fever ranged between 100 and 102 F.; she had no chills or convulsions but she did have a marked parietal headache.

Ten days after admission, signs of an acute mastoditis developed and a left simple mastoidectomy was done under general anesthesia. The mastoid was very large with no destruction of the intercellular septums. Each cell contained thin pus, which was shown subsequently to be beta Streptococcus haemolyticus. Following operation the patient had a sustained febrile reaction which could not be accounted for by the local condition of the ear. Fifteen days after operation she began to complain of pain over the left eye, and at this time the possibility of suppuration of the petrous pyramid was thought of. Examination of the nose and paranasal sinuses did not reveal anything at this time. Twenty days after the original mastoidectomy the mastoid was revised and the petrous pyramid was investigated. Granulations were removed from the sinus plate and middle fossa plate. No tract was visible in and around the semicircular canal. The squama was removed and the dura of the middle fossa was elevated from the superior surface of the petrous pyramid. The ease with which this was done was due to the fact that a large amount of fluid was removed by spinal tap prior to operation. A large gush of nonodorous thick creamy pus was obtained from a pit about half an inch anterior to the arcuate eminence. A rubber drain was inserted and the wound closed. Culture of this pus showed Streptococcus haemolyticus. The patient was given repeated transfusions. Lumbar puncture five days later, because of headache and some rigidity of the neck, revealed evidence of a meningitis with 4,500 cells, 80 per cent polymorphonuclears, 20 per cent lymphocytes and no organisms on smear. The possibility at this time, one month after the original mastoidectomy, of a brain abscess was considered but no localizing signs were found. Repeated spinal taps were done. The patient was placed on large doses of sulfanilamide, the hemoglobin was watched and the content of sulfanilamide in the blood and spinal fluid was determined at regular intervals.

About forty days after the original operation it was first noticed that an anomia and a few changes in the deep and superficial reflexes had developed. Blood cultures were repeatedly negative. At this time brain abscess, loculated meningitis and otitic hydrocephalus were all considered but no definite diagnosis could be made. Because of the persistence of the changes in the spinal fluid, reinvestigation of the wound was done. The dura was seen to be covered by a thick yellow exudate, and on elevation of the dura of the middle fossa a gush of thick creamy pus again appeared. No loculated pockets were found. Because of the persistence of fever and the persistent changes in the spinal fluid and repeated attacks of vomiting and a transient anomia, eight days after the reexploration of the petrous pyramid an exploratory craniotomy for an abscess of the left temporal lobe was performed. Aspiration in several directions in the temporal lobe failed to show any pus. The dura was incised and it was noted that the brain had a peculiar yellow discoloration, but no pus was found. Following the craniotomy the patient's condition was just about the same until a dressing was done ten days later and the probe fell into a cavity in the temporal lobe. A few ounces of thick pus escaped. After

drainage of this abscess cavity the patient's condition progressively improved, the neurologic condition gradually subsided and, except for the peculiar mental changes, the patient appeared to be getting well. Slowly thereafter the spinal fluid cleared up, her mental state returned to normal, her temperature was flat and patient went on to an uneventful recovery with no sequelae other than some diminution of hearing.

This patient had an acute mastoiditis complicated by a suppurative petrositis, a streptococcic meningitis and an abscess of the left temporal lobe. There was a masked clinical picture of an otitic meningitis from the use of sulfanilamide. On a number of occasions, except for a moderate rise in temperature, the patient was symptom free. Physical signs were absent and yet a spinal tap gave definite evidence of meningitis; i. e., increased cells and streptococci.

Until the otitic focus was adequately dealt with, sulfanilamide only partially controlled the meningitis.

This report illustrates a prolonged course (two and one-half months) of meningitis under sulfanilamide administration.

SUMMARY AND CONCLUSIONS

The use of sulfanilamide has resulted in a genuine advance in the treatment of certain otogenous infections.

Exenteration of the otitic focus is of paramount importance.

Indiscriminate use of the drug may obscure the diagnosis or result in a masked or latent clinical picture of mastoid involvement.

Under sulfanilamide therapy, the usual clinical course of an otitic complication may be modified.

1070 Park Avenue.

NOTE ON THE MANAGEMENT OF HYPOPARATHYROIDISM WITH DIHYDROTACHYSTEROL

FULLER ALBRIGHT, M.D.
BOSTON

The criticism is frequently made that metabolic diseases such as those related to the parathyroid glands require for their successful treatment laboratory facilities beyond the reach of all but a very few. It is my object in this note to point out that this is no longer true as regards hypoparathyroidism.

It is perhaps of interest that in hypoparathyroidism and diabetes mellitus there is quite close parallelism as regards the evolution of therapeutics. In both conditions there was a time when the treatment required a great deal of scientific knowledge and laboratory equipment and was none too satisfactory; now the treatment is both simple and satisfactory. Insulin and especially protamine zinc insulin made the difference with diabetes; dihydrotachysterol with hypoparathyroidism. From an academic point of view it is perhaps too bad that the practitioner no longer needs to master ketogenic-antiketognic ratios or the interesting detailed knowledge on the treatment of hypoparathyroidism so well summarized in the classic paper by Ellsworth.[1] One can go a step further as regards the hypoparathyroid patient: It is no longer even necessary that a blood calcium determination be done.

The problem can be very simply stated: All the tetany symptoms of hypoparathyroidism are due to the low level of the calcium of the blood. The goal to be sought is to raise the level of calcium to normal without overdoing the process and obtaining hypercalcemia. Thus all that is needed is an agent to raise the blood calcium level readily to any desired degree and a simple method of gaging this level. Dihydrotachysterol fills the first need and the Sulkowitch test for calcium in the urine the second.

Dihydrotachysterol,[2] like vitamin D, is a photochemical derivative of ergosterol. It was developed by Holz in Berlin for the treatment of hypoparathyroidism. That one can easily raise the calcium of the blood to any desired or even an undesired level with this substance requires no further testimony. The literature was reviewed by Albright, Bloomberg, Drake, and Sulkowitch [3] in a paper which contrasted the action of dihydrotachysterol with that of vitamin D. So much for the therapeutic agent.

Before the means of controlling this therapeutic agent are discussed it will be helpful to list some of the important points in the blood calcium scale. The level of calcium in the serum of a normal person is from 9.5 to 11 mg.; that of a completely parathyroidectomized person from 5 to 7 mg. The normal level of calcium in the serum is above the threshold for the excretion of calcium in the urine; this threshold varies between about 7.5 mg. and 9 mg. Above about 11.5 mg. large amounts of calcium are excreted in the urine and may lead to nephrolithiasis or nephrocalcinosis. At levels of about 16 mg. of serum calcium the danger of sudden death due to hypercalcemia is present.

With these points in mind and with the help of a very simple test (described hereafter) for differentiating urine specimens with no calcium, with a small amount of calcum and with a large amount of calcium, the regulation of the dosage of dihydrotachysterol becomes very easy. The patient with parathyroid tetany, if the diagnosis is correct, should have no calcium in the urine. It should be kept in mind that alkalosis tetany due to hyperventilation is very common and may occur in a patient following an operation on the thyroid. Such a patient will continue to excrete calcium in the urine. Once the diagnosis of parathyroid tetany is made, dihydrotachysterol is administered until the urine tests show moderate amounts of calcium. If large amounts of calcium appear in the urine, the dosage is reduced and the danger of hypercalcemia is avoided.

The Sulkowitch reagent [4] is a solution containing oxalate radicals buffered at such a p_H that when equal amounts of the reagent are added to urine the calcium will almost immediately come down as a fine white precipitate of calcium oxalate. If there is no precipitate there is no calcium, and the serum calcium level is probably from 5 to 7.5 mg. per hundred cubic centimeters. If there is a fine white cloud, there is a moderate amount of calcium and the level of calcium

1. Ellsworth, R.: Diagnosis and Treatment of Parathyroid Underfunction, Internat. Clin. 3: 27, 1933.

2. Dihydrotachysterol is distributed in the United States by the Department of Medical Research of the Winthrop Chemical Company. It is marketed in an oily solution, each cubic centimeter containing 5 mg. of dihydrotachysterol. The preparation is [illegible] mouth

3. Albright, Fuller; Bloomberg, Esther [illegible] witch, H. W.: A Comparison of the Effects of [illegible] Metabolism in Hypoparathyroidism, J. Clin. Investigation 17: 317 (May) 1938.

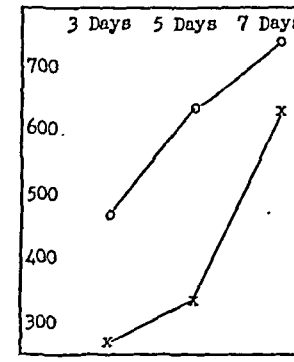
4. Two and five-tenths Gm. of oxalic acid, 2.5 Gm. of ammonium oxalate and 5 cc. of glacial acetic acid are dissolved in distilled water and made up to a volume of 150 cc. (Barney, J. D., and Sulkowitch, H. W.: Progress in the Management of Urinary Calculi, J. Urol. 37: 746 [June] 1937).

in the serum is in the satisfactory range. If the precipitate looks like milk, the danger of hypercalcemia is present.

The patient does his own tests and modifies the dose according to the results. I usually prescribe about 3 cc. of dihydrotachysterol a day until calcium appears in the urine and then I drop the dosage to a maintenance level of about 1 cc. from three to five times a week.

This discussion has been slightly oversimplified. There are a few "ifs" and "buts" that must be added. Occasionally a normal person who happens to be on a very low calcium diet will show in a single specimen of urine practically no calcium. Almost any normal person shortly after drinking a large amount of milk will show an excess of calcium in the urine. Since one keeps one's patients with hypoparathyroidism on a high calcium diet, one would expect them always to show hypercalciuria if their levels of serum calcium are normal. It thus turns out that if the dosage is reduced when a large amount of calcium appears in the urine the blood calcium will be kept at a slightly subnormal level. Such is the case. This is probably all the better, since it further guards against hypercalcemia, and slight hypocalcemia is not deleterious.

Massachusetts General Hospital.



THE INHIBITORY EFFECT OF SULFANILAMIDE ON WOUND HEALING

EUGENE M. BRICKER, M.D.
AND
EVARTS A. GRAHAM, M.D.
ST. LOUIS

The enthusiasm with which sulfanilamide is being used in the treatment of infections of all kinds has tended to minimize a consideration of the possibility of any harmful effects of the drug. Recently the idea has been expressed by many that it might be used prophylactically before certain operations in which the chance of wound infection may be great. It seemed desirable therefore to determine whether or not this drug has any inhibitory effect on wound healing, especially since antiseptics as a group do have such an effect.

The method used was a modification of the technic of Harvey[1] and those working with him[2] in their experiments on wound healing, in which the tensile strength is used as an indicator of fibroblastic growth. Advantage was taken of their finding that there is a "lag phase" of three or four days before fibroblastic growth reaches a maximum velocity and that, in the first three or four days following the making of the wound, determinations of tensile strength are confused somewhat by the effect of suture material. Accordingly, in this experiment the first observations were made seventy-two hours after operation.

Healthy stock dogs were used. Sulfanilamide (para-amino-benzene-sulfonamide, Winthrop) 3 Gm. daily was given for three days prior to operation. This dose ranged between 0.1 and 0.2 Gm. per kilogram of body weight. The drug was given by mouth in 1.5 Gm. doses twice daily. At operation a 2 cm. incision was made into the fundus of the stomach on the anterior surface. The wound was closed with two layers of 000 plain catgut. A blood sample was taken from the treated dogs for sulfanilamide determination. The dogs were killed three, five and seven days after the operation. Blood specimens were taken at this time, and the tensile strength of the wounds was determined. These determinations were made by removing the stomach, clamping off the pylorus and inserting a cannula into the esophageal end. The cannula was connected to a source of compressed air and to a glass U tube. The pressure within the stomach was measured in millimeters of water, and the velocity of air flow was regulated by hand so that the different-sized stomachs would reach their maximum pressure capacity in approximately ten seconds. The level of pressure at which the edges of the wound separated and air escaped from the stomach was observed and recorded. After satisfactory standardization of the procedure, twenty-eight dogs were used for the experiment, fourteen of these being controls.

Tensile strength. The curve plotted with circles represents the control animals; that designated by crosses represents the dogs which received sulfanilamide.

The method of sulfanilamide determination was that described by Marshall and his associates.[3] Some of the values were rather low, however, as shown in the accompanying table. This is explained by the fact that they were usually obtained from twelve to sixteen hours *after the last dose of sulfanilamide, sufficient time* having elapsed for an appreciable lowering of the blood concentration by excretion. It is seen that the dogs received the drug in a quantity comparable to that used therapeutically by human beings. After operation the administration of the drug was continued until the animal was killed.

Concentration of Sulfanilamide in the Blood and Tensile Strength

		Blood Sulfanilamide, Mg. per 100 Cc.		Tensile Strength (Mm. H_2O)		Controls		
	Dog	At Operation	When Killed		Mean Tensile Strength	Dog	Tensile Strength	Mean
Three days	1	8.3	17.3	356		5	510

2. Howes, Edward L.; Socy, Joseph W., and Harvey, Samuel C.: The Healing of Wounds as Determined by Their Tensile Strength, J. A. M. A. **92**: 42 (Jan. 5) 1929.
3. Marshall, E. K., Jr.; Kendall, Emerson, Jr., and Cutting, W. C.: Para-Aminobenzenesulfonamide Absorption and Excretion: Method of Determination in Urine and Blood, J. A. M. A. **108**: 953-956 (March 20) 1937.

tion and the obvious chance for error, this difference is so consistent throughout as to be unquestionable. It can be seen from the figures that fibroblastic growth is inhibited and does not reach its maximum velocity until after the fifth day. By the seventh day, however, the wounds of dogs treated with sulfanilamide were but slightly below those of untreated dogs in tensile strength. From the curves obtained one would judge that had the experiment been carried further a point would have been reached at which the wounds would have been of equal strength.

CONCLUSION

Sulfanilamide, given to dogs in doses comparable to the therapeutic doses used by human beings, has an inhibiting effect on the healing of uninfected incised wounds, as determined by the tensile strength.

SULFAPYRIDINE AND PNEUMONIA

W. M. WHITEHEAD, M.D.
AND
C. C. CARTER, M.D.
JUNEAU, ALASKA

Since the advent of sulfapyridine we have treated three patients with pneumonia with this drug together with other measures and hope that what we have to offer will be of some benefit to others in the treatment of that most dreaded disease.

One patient, a child of 2 years, responded satisfactorily to sulfapyridine without other drastic therapy. The two other patients, both women, became extremely nauseated and vomited after the first dose. The temperature of each was falling but something had to be done to relieve the gastric distress. As continuous operation of the oxygen tent is expensive for the patient, we put them under the tent a half hour before sulfapyridine was administered and kept them there for a half hour after medication, and there was no more nausea or vomiting. The oxygen therapy was continued until the temperature became normal, at which time the dose of sulfapyridine was cut.

The two adults were given two doses of 2 Gm. (30.8 grains) each four hours apart, then 1 Gm. (15.4 grains) every four hours until the temperature became normal and thereafter 0.5 Gm. (7.7 grains) every four hours for two days. The leukocyte count, taken daily, was lowered as the temperature fell.

Another interesting feature of this type of treatment is the fact that digitalis was not used for any of the three patients, whereas as a routine we had been using it for all patients with pneumonia. The time of hospitalization was markedly decreased.

REPORT OF CASES

CASE 1.—Miss M. H., aged 34, admitted to St. Ann's Hospital April 15, having had influenza for one week without improvement, had a temperature of 102 F., a pulse rate of 108 and a respiratory rate of 24. There was considerable cough. Examination of the chest gave negative results.

April 16 examination of the chest, with roentgenograms, showed bronchopneumonia of the left lung. Sulfapyridine 2 Gm. (30.8 grains) was given at 1 p. m., and a mustard plaster was applied. The leukocyte count was 20,200, the temperature 104.6 F., the pulse rate 120 and the respiratory rate 28. The patient was very cyanotic and restless. Morphine sulfate 0.01 Gm. (⅙ grain) was administered by hypodermic. The patient became very nauseated and vomited three hours after the first dose of sulfapyridine. At 5:20 p. m. sulfapyridine 2 Gm. was given. The patient vomited at 6:30 p. m. The sputum, which was rusty, was typed but did not contain pneumococci of types I or II, for which we had specific serum; therefore no serum was given.

April 17 at 8 a. m. the temperature was 97.8 F., the pulse rate 94 and the respiratory rate 20. As the patient was vomiting almost continuously, the use of sulfapyridine was discontinued and dilaudid was used instead of morphine for the restlessness. The sputum was clear in color. At 7 p. m. the leukocyte count was 19,550. The temperature began to rise, and sulfapyridine tablets were crushed and given in peppermint water, but the patient immediately vomited.

April 18 at 8 a. m. the temperature was 102.2 F., the pulse rate 112, the respiratory rate 24 and the leukocyte count 16,400. The patient was very cyanotic and the sputum rusty. She was put under an oxygen tent and the administration of sulfapyridine 1 Gm. started. She did not become nauseated or vomit again.

April 19 at 8:30 p. m. the temperature was 98.6 F., the pulse rate 84, the respiratory rate 20, the leukocyte count 15,300 and the erythrocyte count 4,310,000.

The oxygen tent was used for only one-half hour before and after medication, and its use was completely discontinued on the morning of April 20. The administration of sulfapyridine was discontinued April 21. The leukocyte count was then 12,650. The patient had had no fever for two days. Daily examinations of the urine showed a 1 plus reaction for albumin.

April 24 the patient was allowed out of bed, and April 27 she was discharged from the hospital.

The time of hospitalization was twelve days.

CASE 2.—J. E. Jr., aged 2 years, admitted to St. Ann's Hospital April 19, had a rectal temperature of 102 F. at 8 a. m. A diagnosis of bronchopneumonia of the right lung was confirmed by x-ray examination. Sulfapyridine was given, 0.5 Gm. (7.7 grains) in the first dose and 0.25 Gm. (3.9 grains) every four hours thereafter. The temperature was normal April 21 at 6 a. m., at which time the dose of sulfapyridine was reduced to 0.13 Gm. (2 grains) every four hours. This dose was administered until April 25, when the patient was discharged from the hospital.

The oxygen tent was not necessary for this patient. No blood counts or urinalyses were done.

The time of hospitalization was six days.

CASE 3.—Mrs. P. E., aged 20, admitted to St. Ann's Hospital April 27, having been sick for four days at home with "the flu," had a temperature of 104 F., a pulse rate of 120 and a respiratory rate of 32. She was cyanotic and coughing. A diagnosis of lobar pneumonia involving two thirds of the left lung was made and confirmed by x-ray examination. Sulfapyridine 2 Gm. and dilaudid for rest were given at 8:30 p. m. The patient became nauseated and vomited two hours later.

April 28 at 12:30 a. m. sulfapyridine 2 Gm. was given. The patient vomited at 3:30 a. m. Sulfapyridine 1 Gm. was given at 4:30 and 8:30 a. m., but the patient was nauseated and vomited almost constantly. The oxygen tent was therefore used for one-half hour before and after medication. From 8:30 a. m. April 28 the patient was completely free from nausea and vomiting. The leukocyte count was 18,550, the temperature 102 F., the pulse rate 116 and the respiratory rate 28.

On the morning of April 29 the leukocyte count was 25,800, the temperature 101 F., the pulse rate 120 and the respiratory rate 26, but by 4:30 p. m. the temperature was normal, the pulse rate 90 and the respiratory rate 22. The use of the oxygen tent was discontinued and the dose of sulfapyridine cut to 0.5 Gm. every four hours.

April 30 the leukocyte count was 12,050 and the patient was feeling very well. The use of sulfapyridine was discontinued May 1. The patient was allowed out of bed May 2 and discharged from the hospital May 3. Daily urinalyses showed a 1 plus reaction for albumin.

The time of hospitalization was six days.

SUMMARY AND CONCLUSIONS

The number of cases reported is very small, but the results were so striking that other physicians may derive benefit from the use of oxygen with sulfapyridine.

The patients were placed in the oxygen tent for one-half hour before and after medication, with complete relief of nausea and vomiting and marked alleviation of the cyanosis.

No experimental work or blood chemistry determinations, such as testing the carbon dioxide-combining power, was done to ascertain the reason for the relief of nausea and vomiting following the use of the oxygen tent. Undoubtedly the sulfapyridine produced the nausea and vomiting.

The time of hospitalization was greatly reduced.

No complications developed in any of the three cases.

The oxygen tent might well be used with every dose of sulfapyridine until the temperature becomes normal.

BLOOD SUGAR VERSUS URINE SUGAR

AS OBSERVED IN PATIENTS TREATED WITH PROTAMINE ZINC INSULIN AND WITH ORDINARY INSULIN

ANTHONY SINDONI JR., M.D.
Chief of Diseases of Metabolism of the Philadelphia General and St. Agnes Hospitals; Chief Metabolic Consultant at the American Oncologic Hospital
PHILADELPHIA

(Concluded from 2508)

SUMMARY OF OBSERVATIONS

1. None of the patients in table 1 at any time during examination of the urine within the three hour period after breakfast excreted dextrose in spite of the increased blood sugar. In many of the patients the blood sugar was above the normal level after meals. Patients on protamine and ordinary insulin maintained higher blood sugar levels postprandially without glycosuria than those on either form of insulin alone, or those without insulin. Two of the patients without insulin maintained increased blood sugar levels above normal without glycosuria.

2. Many patients in table 2 averaging elevated blood sugar levels above normal after meals excreted less dextrose in the urine than many of those patients averaging lower elevations of blood sugar but still above normal. This was more common in patients on protamine and ordinary insulin. These observations also occurred in many of the patients in tables 3 and 4.

An interesting observation made in the individual blood sugar examinations of the patients at the end of the first and second hour was the marked fluctuations in the blood sugar levels not only in different patients but also in the same patient on different days of our examination. These bore no corresponding relationship to the amount of glycosuria and could not have been detected by examinations of sugar in the urine.

Thus, during an individual study of case 56 in table 2, the patient, on protamine zinc insulin alone, in one of our examinations at the end of the first and second hour had a blood sugar level of respectively 162 mg. and 172 mg. per hundred cubic centimeters with 0.7 Gm. of dextrose excreted in the urine. In the same patient a few days later, at the end of the first and second hour, it was respectively 284 mg. and 370 mg. with 0.6 Gm. of dextrose in the urine. In case 15 in table 2 during a similar study, but on ordinary insulin alone, at the end of the first and second hour it was 320 mg. and 234 mg. respectively with 0.7 Gm. of dextrose in the urine; a few days later it was 296 mg. and 212 mg. respectively with no spill or excretion of dextrose in the urine. Similar results occurred frequently throughout our studies.

3. It is also interesting to note that we have observed on rare occasions low blood sugar levels after meals with urine positive for dextrose. An example is the case of a man aged 22 on protamine and ordinary insulin whose postprandial (two hours after breakfast) blood sugar was 66 mg. per hundred cubic centimeters with 0.5 Gm. spilled in the urine.

We have also observed in our wards low postprandial (two hours after breakfast) blood sugars, not infrequently at a hypoglycemia level, with no apparent symptom. This is exemplified in a girl aged 14 years, being observed on protamine and ordinary insulin, whose blood sugar was 37 mg. per hundred cubic centimeters and who was symptom free with a negative urine for dextrose, probably because she was inactive and resting in bed. On another occasion with less insulin she had mild shock symptoms, such as an increased sense of warmth and slight nervousness, with a blood sugar two hours after breakfast of 55 mg. per hundred cubic centimeters.

4. We have also observed patients (table 3) with variable average blood sugar levels who excreted approximately the same amount of dextrose in the urine. These variable blood sugar levels averaged from 166 to 330 mg. per hundred cubic centimeters at the end of the first hour after breakfast with an approximate average excretion of dextrose in the urine between 1.4 and 1.9 Gm. These results occurred more frequently in the patients on protamine and ordinary insulin, although not infrequently in those on ordinary insulin alone.

5. We have also observed patients (table 5) whose individual blood sugar elevations above normal in the first and second hour after breakfast varied markedly with little or no change in the dose of insulin. These patients also showed at different intervals extreme variations in the amount of excretion of dextrose in the urine, as from 0 to 3.7 Gm., the excretion bearing no relationship to the fluctuations of the blood sugar levels. Such observations were more common in the patients on protamine and ordinary insulin than in those on ordinary insulin alone. Thus in case 12 of table 5 (on protamine and ordinary insulin) the blood sugar at the end of the first and second hour was respectively 280 mg. and 268 mg. per hundred cubic centimeters with no excretion of dextrose in the urine; on another day it was 230 mg. and 138 mg. per hundred cubic centimeters with 3.7 Gm. of dextrose excreted in the urine; still another day it was 410 mg. and 338 mg. with 1 Gm. of dextrose spilled.

We have also observed patients on protamine and ordinary insulin (case 29, table 4) whose averaged blood sugar at the end of the first and second hour was 219 mg. and 169 mg. per hundred cubic centimeters respectively, with an average excretion of 14.07 Gm. of dextrose in the urine. In case 54 (table 4), on ordinary insulin alone, the average blood sugar level was respectively 289 mg. and 280 mg. per hundred cubic centimeters, with an average excretion of 23 Gm. in the urine. In case 12 (table 5), on protamine and ordinary insulin the blood sugar level at the end of one and two hours was 410 mg. and 338 mg. respectively, with excretion of 1 Gm. of dextrose, but a few days previously the blood sugar was 280 mg. and 268 mg. per hundred cubic centimeters with no excretion of sugar.

6. In the twenty-four hour urine study we observed patients with blood sugar levels elevated above normal, one and two hours after breakfast, but with no sugar in the urine. These observations were made not infrequently in the large group of diabetic patients who were on both forms of insulin (protamine and ordinary). The highest postprandial blood sugar levels with a negative twenty-four hour urine was observed in the patients on ordinary insulin alone; lower levels with negative twenty-four hour urine were observed in the patients on protamine and ordinary insulin. At not uncommon intervals the latter level was at a hypoglycemic point without symptoms of insulin shock.

7. On rare occasions patients on protamine and ordinary insulin were observed with a low postprandial blood sugar, 66 mg. per hundred cubic centimeters, but with sugar in the urine. In these cases, if the sugar in the urine alone was the determining factor for adjusting the insulin dose, the patient would probably have received an increased dose and be subjected to serious consequences. An interesting finding was that many patients on the protamine and ordinary insulin maintained postprandial blood sugar levels above the normal level but the urine was normal within three hours after breakfast and in the twenty-four hour urine study.

INTERPRETATION OF OBSERVATIONS

In reviewing the literature we find it replete with controversy as to the significance of sugar in the urine and the relation of such sugar to glycemia. Our own observations confirm those of many of the references given that disturbance in the blood sugar concentration is the first apparent manifestation of the disturbances to be corrected in diabetes. The urine sugar, whose source is the blood sugar, not uncommonly is an unstable quantity bearing no corresponding relationship to the blood sugar level or concentration. Probably this absence of definite quantitative relationship between blood sugar and urine sugar in diabetic patients is due to disturbances affecting kidney functions. Thus:

(*a*) Kidney function may be depressed or interfered with by "extrarenal" disorders, such as heart disease, severe general anemia, hypertrophied prostate, cystitis [21] and the like. Or it may be depressed or interfered with by "intrarenal" factors, such as variation in the degree of concentration of dextrose in the plasma, or the volume of the glomerular filtrate or of renal activity [3] affecting the filtration-reabsorption process. If only a relatively few glomerulotubular units are active, Sherrill and MacKay [3] feel that it is reasonable to suppose that a much higher concentration of dextrose in the plasma would be required to cause sugar to appear in the urine than if the kidneys were fully active. On the other hand they feel that, with all the renal elements functioning, diuresis might so reduce the reabsorption of dextrose that a concentration of dextrose in the plasma considerably lower than usual might be reached before sugar-free urine would be formed. Page and Corcoran [5] are under the apprehension that the only true "extrarenal" disturbance which might alter the excretion of dextrose is a decrease in glomerular filtration to the point at which little filtrate is formed—a situation not infrequent in diabetic coma with vasomotor failure, in which dextrose may disappear from the urine. This state they say passes rapidly into one in which no glomerular filtrate is formed and the patient is anuric. Gopfert [32] believes that in the course of diabetic coma there is a disorder in the renal activity which is responsible for many of the complications that occur. He is also of the opinion that probably this disorder is in conjunction with circulatory disturbances and metabolic anomalies that work together and, depending on the predominance of the one or the other, cause different symptoms to predominate.

(*b*) Blatherwick and Medlar [33] have shown through animal experiments that functional impairment of the kidney may exist for some time before histologic changes indicative of nephritis become apparent. They suggested that the initial impairment of the kidney may be a change in the functional activity of the glomerulus. The injurious factor responsible for this either may exist in the diet or may be produced during metabolism. The consequences of this observation become more evident when one considers that in view of the increasing incidence of premature arteriosclerosis shared generally by the body, including the kidneys, the disturbed diabetic metabolism is not completely corrected by insulin and diet. Local infections, however trivial or insignificant they may be to the nondiabetic person, must be guarded with the greatest fear by the diabetic patient against the possibility of their becoming generalized and bringing about a dangerous state.

From clinical data we infer that the apparently normal metabolism in diabetes in the absence of complications is in reality abnormal. Thus in the presence of infection it behaves in a manner somewhat similar to the metabolism of an untreated diabetic person [34] in spite of the insulin and diet. Hence why cannot the abnormal metabolism in diabetes, in spite of the apparent normality, be a factor responsible for the alteration of kidney function in such a manner that the quantitative sugar excretion bears no relationship to the level of blood sugar as shown by our studies? This also becomes more apparent when one realizes the large number of cases presenting concomitant pathologic changes of the kidney which form a part of the generalized arteriosclerosis in diabetes as revealed at postmortem examination. Warren's [34] incidence of arteriosclerosis in 300 fatal cases of diabetes showed forty-nine with a slight degree of either arteriosclerotic or chronic progressive (arteriosclerotic) nephritis, forty-seven with moderate pathologic changes and only eleven with marked pathologic changes. Stewart and McIntosh's [35] studies on renal function revealed that nineteen of twenty patients with arteriosclerotic or hypertensive heart disease had impaired renal function. Warren [34] emphasizes the fact that the kidneys of those in the older age groups are frequently already impaired when they are needed to effect the maintenance of acid-base equilibrium.

(*c*) Still one may have functional impairment in the absence of pathologic changes. Experiments in animals have shown that functional impairment of the kidneys may exist for some time before histologic changes become apparent.[33] This functional disturbance without histologic or pathologic changes probably may be compared to the pancreas, in which there is a frequent absence of demonstrable pathologic changes responsible for the diabetic condition or functional disorder of the insulin mechanism.

35. Stewart, H. J., and McIntosh, J. F.: The Function of the Kidneys in Patients Suffering from Cardiac Disease Without Signs of Heart Failure, J. Clin. Investigation **6**: 325 (Oct.) 1928.

Warren [34] states that practically any lesion found in the pancreas of the diabetic patient involving either the island tissue or the acinar tissue or both can be duplicated in the pancreas of nondiabetic persons. These observations are noteworthy when one realizes that the kidneys are functioning in a more or less constant environment of disturbed carbohydrate metabolism, a factor, probably, in spite of its apparent normality, in bringing about renal functional disturbances as related to renal threshold and with the problem of the relationship of glycosuria to glycemia with or without definite pathologic changes. Elliot and Nuzum [36] believe that one cannot separate the kidney from a constantly changing circulatory environment on which its functional response must in great measure depend. Epstein [37] says that there is no a priori reason to believe that the utilization of sugar in the kidney differs in any way from that of any other organ or tissue. He says that there are frequently encountered cases of diabetes which show no evidence of renal disease, in which the glycosuria disappears spontaneously or as the result of treatment but in which a hyperglycemia persists.

(*d*) Renal functional tests are of little or no aid in revealing true functional disorders of the kidney or the extent of pathologic changes. Levinson and MacFate [21] feel that such tests as the phenolsulfonphthalein or the urea clearance simply measure the function of the kidney in respect to that specific substance and not the extent of anatomic changes in the kidney and that they are not an absolute criterion as to how the kidneys will excrete the normal or abnormal products of metabolism. Elliot and Nuzum [36] feel that the more sensitive the test of function, the more it may be influenced by factors—changing vascular tone and decreased cardiac reserve—and therefore the more difficult is the interpretation in the terms of renal pathologic conditions. Statistical conclusions regarding the incidence of faulty renal function in patients with hypertension, they say, will vary so greatly with the tests used and with the manner of their interpretation as to mean little or nothing.

Patients on protamine zinc insulin therapy may have sugar-free urine in the morning before breakfast and feel fine but may have a low blood sugar, even to a level of hypoglycemia, without symptoms. This may also occur between meals if the interval is prolonged, as in a case we observed of a patient, aged 59 years, on protamine and ordinary insulin, with a postprandial blood sugar (two hours after breakfast) of 37 mg. per hundred cubic centimeters and also of a girl, aged 15 years, with a blood sugar (two hours after breakfast) of 25 mg. per hundred cubic centimeters without symptoms. This interval with the blood sugar at the level of hypoglycemia, however mild it might appear to a diabetic patient, may cause damage to the cardiovascular and neurologic systems. Kepler and Moersch [38] claim that there occur not only transitory changes in the nervous system but also irreversible changes of a permanent character, possibly as the result of frequent and severe hypoglycemic reactions.

If a hypoglycemic state should occur during sleep when the patient is at complete rest, there would be little likelihood of warning symptoms—a dangerous state of affairs. Wilder [39] records several instances of patients awakening in the morning with sore, stiffened muscles, a bitten tongue and attacks with convulsions. He speaks of being informed of one death following protamine zinc insulin and fears that others will follow unless great pains are taken to impress patients with the importance of heeding early symptoms and combating them with carbohydrate. Wilder cites Bollman's experiments with animals that died from fatal convulsions caused by protamine zinc insulin in which he found multiple petechial hemorrhages scattered throughout the brain. Sherrill and MacKay's [40] observations on animals that died of protamine zinc insulin shock found grossly no particular abnormality of the brain. In reporting the untoward effects of hypoglycemia, they compare the damage to that due to anoxemia.

(*e*) Another dangerous possibility, if the procedure is restricted to examination of the urine, is that one may confuse the not infrequent symptomless hypoglycemic state caused by protamine and ordinary insulin therapy for hyperglycemia, especially if the urine is positive. If the patient excretes sugar in the urine, as in the case of a young man with a postprandial blood sugar (two hours after breakfast) of 66 mg. per hundred cubic centimeters, it would add to the difficulty of making the correct diagnosis. In such a state, if the patient had symptoms of discomfort or mild signs of insulin reaction, his condition might be diagnosed as showing an increased blood sugar with the result that the physician might be tempted to increase the insulin dose, thereby producing serious consequences. Wauchope [41] reported a fatal hypoglycemia due to mistaken diagnosis when more ordinary insulin was prescribed. Leyton,[42] in reporting a case in which glycosuria occurred in spite of the hypoglycemia, stresses the practical importance of this, because if one were to cease giving sugar when sugar appeared in the urine the patient would die from hypoglycemia. Jackson and Boyd [43] speak of a patient who died at home under circumstances which strongly indicate that death was attributed to hypoglycemia brought on by protamine zinc insulin. Lindsay and his associates [44] reported a fatal case due to hypoglycemia as a result of protamine zinc insulin. Jonas [45] also reports a case of fatal hypoglycemia due to insulin after it had been discontinued eleven days. Joslin and his co-workers' [46] comment on a case of fatal hypoglycemia mistaken for diabetic coma was that if the urine had been obtained when the patient was admitted to the hospital it would not have solved the differential diagnosis between coma and hypoglycemia, because often the first specimen of urine voided by the hypoglycemic patient contains sugar, having been secreted perhaps hours earlier by the kidneys. Joslin,[47] in describing four deaths due to hypo-

glycemia in children, speaks of one of them as caused by a mistaken diagnosis for diabetic coma in which the patient received 200 units of insulin from a physician who had never seen a case of coma or of any insulin reaction. Root [48] describes the serious effects of insulin hypoglycemia on a heart damaged by coronary disease. He speaks of a patient who received by error an overdose of insulin which proved to be fatal. Ernstene and his co-workers [49] observed that the heart rate is reduced to 50 or 25 per cent of its normal value during these hypoglycemic states—a factor for diminished circulatory rate through the brain. Wohlwill [50] and Beck [51] reported an instance of a patient who suddenly went into fatal insulin shock from diabetic coma. Leyton [42] reported the case of a child aged 5½ years who had been in coma and been restored by insulin. Severe hypoglycemia developed which persisted for ten or eleven weeks, although administration of insulin had been stopped. His symptoms ceased after seven weeks, but the glycosuria was present throughout the entire hypoglycemic state.

(*f*) Cases of marked instability of the blood sugar level were occasionally encountered. In these instances only frequent blood sugar estimations averted severe hypoglycemic reactions. Urine sugar examination alone in such cases would have been a dangerous procedure. Even with the blood examination it was almost impossible at times to preserve the mean between hyperglycemia and hypoglycemia. This occurred not only with protamine and ordinary insulin alone but also in the patients on both forms of insulin.

Patients may have, as observed in the foregoing groups, increased blood sugar above normal with sugar-free urine or urine slightly positive for sugar after meals as well as a "negligible" quantity in twenty-four hour urine. The physician may advise the patient to ignore the trace of sugar in the urine as it is of "no significance." He may be prompted to say this because to allow the presence of sugar in the urine after meals may eliminate the danger of insulin shock or reaction in patients on protamine zinc insulin. This glycosuria is also not infrequently seen in the patient on protamine alone or with ordinary insulin who may have the morning fasting urine sugar free and feel that the diabetes is under good control but, following his meals, he may spill a variable amount of sugar. Wilder,[30] Kepler,[52] Lawrence,[53] Himsworth [54] and others admit the inability of the protamine zinc insulin alone to control the hyperglycemic effects of meals in spite of the fact that the morning urine may be sugar free and the dose of protamine zinc insulin so large that it will provoke a night reaction. They feel that, if the patient is maintained constantly sugar free, reactions of severity are inevitable. Such "control" may probably help to eliminate insulin reactions to an extent, but when one considers that there has been observed in patients after breakfast as well as in the twenty-four hour urine a blood sugar concentration above normal with urine negative for sugar and much higher blood sugar levels with excretion of varying "insignificant" amounts of dextrose, one wonders whether this is controlled at all, especially in view of the increasing diabetic complications.

Of course, the optimum result in the treatment of diabetes is to metabolize the prescribed diet with a postprandial blood sugar that approaches the normal without regard to the analysis of the urine. That this is not always accomplished and that effective diabetic treatment today is far from being well achieved in spite of the new advances—insulin, ordinary or protamine, higher carbohydrate diet and the like—is painfully apparent when one considers the increasing mortality and number of elderly diabetic patients who are becoming invalids either from diabetic gangrene, coronary disease or cataracts. According to Major's [55] statistics the death rate from diabetes mellitus in the registration area of the United States for 1919, three years before the introduction of insulin, was 14.9 per hundred thousand, while the rate in 1925, three years after the introduction of insulin, was 16.9. Comparisons of the ratio of diabetic deaths to total deaths in Massachusetts shows that the ratio in 1920 was 0.86 while in 1925 it was 1.56, or nearly twice as high. Encouragement, however, is given in a study of the age group by the fact that the mortality from juvenile diabetes is distinctly lowered. These observations are somewhat in accord with our observations. Joslin and his co-workers [56] admit that the death rate in diabetes is still much in excess of that for the general population. Also the increase in expectation of life is progressively less with advancing age. The diabetic patient in spite of insulin has not been freed from the entanglements of premature arteriosclerosis and all its allied degenerative lesions. Nevertheless, in spite of these levels of blood sugar above normal in which there is sugar-free urine, many investigators are inclined to believe that protamine zinc insulin alone by its continued action, as based on twenty-four hour urine, will further delay the onset of premature arteriosclerosis. This point of view I decline to accept as a method of adequately controlling a diabetic patient as long as an increased blood sugar level above normal after meals exists with normal urine or a trace of sugar in the fasting, twenty-four hour or postprandial urine. For, surely, if this increased blood sugar above normal, escaping detection by urine tests, is allowed to continue months or years it will probably help to increase the prevalent degenerative complications—premature arteriosclerosis, diabetic ulcer, gangrene or coronary disease.[28]

But has insulin failed to come up to expectations in diabetic treatment or have physicians failed to recognize adequately the role of the disturbed metabolism by gliding over the importance of making chemical examination of the blood? My inference is that the latter is true. The disturbed metabolism cannot be adequately recognized and corrected by determination and correction of urine sugar alone, whether it is of fasting, postprandial or a twenty-four hour specimen. Kepler [52] takes the position that until the cause of arteriosclerosis and allied degenerative lesions is determined one is not justified in assuming that glycosuria is not detrimental to health. Insulin (protamine or ordinary) is not at fault. It is the greatest adjuster adequately

applied after blood sugar determination, will help better to decrease the degenerative diabetic complications and mortality rate and finally will aid in making more rapid progress into the possible etiology of diabetes.

We take the position that examination of the urine for sugar as indicative of the degree of blood sugar concentration or carbohydrate disturbances is not to be depended on, for it may be misleading. Diabetic control by urine sugar alone is to be considered not without dangers of unwarranted end results and even with the possibility of fatal hypoglycemia.

DISADVANTAGES OF DETERMINATION OF URINE SUGAR FOR CONTROL OF DIABETES

1. The presence of sugar in the urine does not always exclude a diagnosis of hypoglycemia nor does it always signify diabetes mellitus—perhaps so-called "renal diabetes" or benign glycosuria.

2. A normal urine does not exclude the diagnosis of hypoglycemia in patients on protamine zinc insulin, or after meals in those patients on ordinary and protamine zinc insulin combined, nor does a normal urine eliminate a diagnosis of hyperglycemia.

3. A normal twenty-four hour urine after a regular prescribed diet does not always indicate adequate control of diabetes.

4. "Interpretation" of a trace of sugar in the urine or normal urine without blood examinations may result in improper administration of insulin and mismanagement of the disturbed blood sugar level, hence further adding to inadequate control of the carbohydrate metabolism—either by producing frequent hypoglycemic states and their serious ultimate effects or by frequent hyperglycemia, probably helping to increase the prevalence of premature arteriosclerosis and their associated end results of various degenerative changes, thereby adding to the mortality rate. Thus, just to cite one of the many patients who came under our observation, a woman aged 67 had for years been under the care of a physician who "controlled" her diabetes (diet, activities and the like by examination of the urine). Because of the normal urine, or occasionally of a trace of sugar, which the physician probably considered "of no significance," he did not deem it advisable to undertake an estimation of the blood sugar. When the patient entered our diabetic ward she had diabetic gangrene of the left foot which necessitated a midthigh amputation. Her postprandial blood sugar (two hours after breakfast) was 340 mg. per hundred cubic centimeters.

5. Sugar in the urine is usually interpreted in terms of elevated blood sugar levels. Thus a large amount may be interpreted as a markedly elevated blood sugar, a small amount as moderately elevated. In reality, the former may occasionally, or in fact not infrequently does, show a lower blood sugar than the latter, as revealed by our studies.

6. During coma the patient usually cannot void, and catheterization in such a state for the estimation of sugar is a dangerous procedure because infection of the bladder and genito-urinary tract is not uncommon in diabetic patients. Wauchope [41] speaks of diabetic coma that may occur with profound acidosis in the absence of glycosuria. Kidney function in such states is frequently impaired, owing to toxic injury by products of the abnormal metabolism to the epithelial cells. Gopfert [32] believes that there is a disorder in the renal activity which is responsible for many of the complications that occur. Blatherwick and Medlar's [33] studies of the kidney established the existence of essential changes in the glomerulus and tubules, an impairment that may be brought about as a result of overwork or during metabolism. I believe that the renal impairment, probably the glomerular changes affecting the filtering apparatus, is due perhaps to the marked metabolic disorders that occur in coma or in prolonged hyperglycemia. These metabolic disturbances or irregularities will probably add much in interfering with renal function in such a manner as to cause a loss of quantitative relationship of glycosuria to glycemia.

7. During acute complications—as in infections or surgical conditions—a specimen of urine may be difficult to obtain. Catheterization in such cases would be perhaps a dangerous and unreliable procedure.

8. Drugs may effect a reduction in glycosuria without causing any significant change in the concentration of the blood sugar in diabetes either during fasting or after the ingestion of dextrose; for example, dinitrophenol.[57] The experiments of Kleiner and Meltzer [58] on a group of animals are of interest in that they show by intravenous injection of fourth-molar solution of magnesium sulfate that glycosuria was very little marked and far under proportion to the marked hyperglycemia produced, and often the glycosuria was entirely absent.

9. Cases of diabetes with definite renal disease frequently show no relationship between the hyperglycemia and the glycosuria.[59] The hyperglycemia in such persons is usually greater in proportion to the glycosuria than in those diabetic patients with apparently normal functioning kidneys.

10. Frequent examination of the urine for sugar after one or more meals or on retiring or rising may cause much mental anguish and probably bring about a peculiar mental state. This not infrequently causes the patient to become too diabetes conscious and may hinder his progress.

CONCLUSIONS

No apparent quantitative correspondence existed between the blood sugar and the urine sugar in a large number of patients on protamine zinc insulin and ordinary insulin alone or on the two combined, or without insulin as observed in our studies after regular prescribed meals. Probably renal functional disturbances, which frequently escape detection by laboratory or physical means, brought about by the disturbed carbohydrate metabolism, were sufficient to interfere with the excretion of sugar in such a manner as to cause a partial loss and, at times, a marked loss of quantitative relationship between the urine and the blood sugar.

1. Quantitative increase of dextrose in urine after breakfast in patients on protamine and ordinary insulin or on the two combined may alarm the physician into thinking that the patient has a markedly elevated blood sugar; or, on finding a small quantity, he may interpret it in terms of slightly increased blood sugar. In reality it may be as we observed in a patient who had 289 mg. per hundred cubic centimeters the first hour after breakfast with 23 Gm. of dextrose in the urine, while in another patient on protamine and ordinary insulin

57. Wishnofsky, Max; Kane, A. P.; Shlevin, E. L., and Byron, C. S.: Influence of Di-Nitrophenol on Carbohydrate Metabolism, Arch. Int. Med. **56**: 374 (Aug.) 1935.

58. Kleiner, I. S., and Meltzer, S. J.: On the Production of Hyperglycemia and Glycosuria by Magnesium Salts, Proc. Soc. Exper. Biol. & Med. **13**: 1103 (Dec. 15) 1916.

it was 410 mg. per hundred cubic centimeters with 1 Gm. of dextrose in the urine. With protamine zinc insulin alone we observed that a patient two hours after breakfast spilled 2.1 Gm. in the urine with a blood sugar of 142 mg. per hundred cubic centimeters; in another patient the blood sugar was 271 mg. with a 0.6 Gm. spill.

Similar observations were obtained in the twenty-four hour urine study. Thus excretion of 3.4 Gm. of sugar was found in a patient on protamine and ordinary insulin with a postprandial blood sugar (two hours after breakfast) of 224 mg. per hundred cubic centimeters, while in another patient it was negative with a postprandial blood sugar of 308 mg. These observations occurred not infrequently in the same patients but also in different patients with either form of insulin alone.

2. A normal urine does not eliminate the diagnosis of hypoglycemia. Patients taking protamine with ordinary insulin can maintain a lower blood sugar level than they can on either ordinary or protamine zinc insulin alone, and at times hypoglycemic levels before breakfast and between meals, without any apparent symptoms which cannot be detected by urine examination. With protamine zinc insulin alone, fasting blood sugar has been maintained at a lower level than with ordinary insulin. Such a hypoglycemic state escaping detection by urine examination alone, and allowed to continue at frequent intervals for an indefinite period, may, as shown, prove of serious consequences.

3. The amount of sugar in fasting, postprandial or twenty-four hour specimen of urine should not be depended on:

(*a*) To interpret or correlate blood sugar levels or concentration. (No corresponding quantitative relationship was found between blood sugar and urine sugar in patients on protamine or ordinary insulin or on the two combined or without insulin in our observations of the sugar in blood and urine after meals in patients on higher carbohydrate diets.)

(*b*) To judge insulin (protamine and ordinary) dosage or control the disturbed blood sugar fluctuation, because (1) of the danger of the presence of hypoglycemia with urine positive for sugar resulting in serious consequences; (2) normal urine, whether in fasting or in twenty-four hour specimens, does not show the occasional or not infrequent elevated blood sugar above normal or frequent higher "peaks" or levels after meals.

4. In view of the high incidence of disturbed carbohydrate metabolism frequently escaping detection by examination of the urine for sugar and the serious consequences resulting therefrom, blood sugar estimations, fasting and after meals, should be indispensable in early and latent recognition and treatment of the blood sugar disturbances:

(*a*) They should be the governing factor in guiding the insulin dose and diabetic treatment.

(*b*) Control of the hyperglycemia, not the glycosuria, should be the paramount aim of diabetic treatment. This is not difficult when one considers the hundreds of diabetic patients on protamine and ordinary insulin combined or alone, coming to clinics every four to eight weeks a distance of many miles from the hospital. This is more true of the private patients coming a distance of hundreds of miles once every six to twelve weeks with little or no risk of hypoglycemia or insulin reactions.

5. An increased blood sugar level above normal or frequently higher levels after meals, a definite sign of disturbed carbohydrate metabolism, not revealed adequately by urine sugar, is to be considered in the absence of definite etiology of arteriosclerosis a pathologic disorder probably helping to precipitate premature arteriosclerosis in diabetes.[28] The increased incidence of diabetic complications such as premature arteriosclerosis, gangrene and coronary sclerosis, in spite of insulin and improved therapy, leads to the realization that one should concentrate more on blood chemistry and less on urine sugar.

6. There exists a welter of confusing theorization about the method of interpreting the dextrose in the urine as related to the blood sugar concentration. The renal "threshold" for dextrose is still a subject of much controversy and is an unsettled problem among various investigators throughout the world. From our observations, after meals, of the regulated prescribed diets in diabetes we feel that if a renal threshold exists it is variable not only in the same patient but also in different patients. The mechanism responsible for this variation of renal "threshold" in diabetes is unknown, but probable factors which may influence it are (*a*) constantly changing circulatory environment on which the renal functional response depends,[36] (*b*) the presence of infections, (*c*) infections complicated or associated with hypertensive heart disease, (*d*) arteriosclerosis, (*e*) probably disturbances of the utilization of sugar by kidneys in similar way as of other tissue,[37] (*f*) age—in the older age group as compared with the young the kidneys are frequently already impaired,[34] (*g*) acidosis or coma, (*h*) prolonged hyperglycemia, as in long continued, mild, uncontrolled diabetes or in irregularly controlled severe disease,[5] (*i*) insulin, (*j*) diet, (*k*) kidney and bladder disease, (*l*) anemia,[21] (*m*) exercise,[60] (*n*) neurologic disturbances,[61] (*o*) endocrine factor,[62] (*p*) hypoglycemia states, (*q*) drugs,[63] (*r*) individual variations and (*s*) pregnancy. Page and Corcoran[5] state that it is impossible to assume that the kidney is normal in diabetic patients with arteriosclerosis whether uncomplicated or associated with hypertension or chronic nephritis and also in those with an infection, although the available tests of renal function may not show evidence of marked abnormality.

Thus in spite of such disadvantages in taking blood sugar tests as (1) complicated apparatus or equipment as compared with the simple equipment necessary for urine sugar examination, (2) the fact that the apparatus cannot be transported as easily as apparatus for the estimation of sugar in the urine, (3) the fact that blood specimens must be obtained by a technician or a physician and be examined by a laboratory technician or physician and not by the patient, (4) the complicated technical procedure for blood sugar estimations and (5) the fact that there is danger of infection when blood is taken, it is nevertheless most important to examine the blood for sugar because of the significance and accuracy of the information it gives as to the true state of the diabetes.

Clinical Notes, Suggestions and New Instruments

HEMOCHROMATOSIS: DIAGNOSIS AT AUTOPSY, DEATH BEING DUE TO PERFORATED DUODENAL ULCER

C. H. BINFORD, M.D.
AND
W. E. SHARPE JR., M.D.
Passed Assistant Surgeon and Assistant Surgeon, Respectively, United States Public Health Service, U. S. Marine Hospital
DETROIT

A recent review[1] of the literature of hemochromatosis since the monograph of Sheldon[2] reports altogether 387 acceptable cases of the disease on record.

We add an additional case, in which hemochromatosis was an unexpected observation at autopsy following death from a perforated duodenal ulcer.

REPORT OF CASE

History and Examination.—J. W. S., a white man aged 52, a brewery worker, admitted to the hospital Sept. 15, 1937, complained of an umbilical hernia which had gradually increased in size. He stated that he drank beer moderately. He had been told several years previously that he had diabetes.

Except to reveal a blood pressure of 165/100 and a fairly large umbilical hernia, the routine physical examination at admission gave essentially negative results. The first urinalysis showed a slight trace of sugar, but repeated subsequent examinations showed none. The Kahn reaction of the blood was negative.

Course.—Two days after admission, repair of the umbilical hernia was begun. When the peritoneum was incised 500 cc. of straw-colored fluid escaped from the abdominal cavity. The liver was small, firm and nodular. An omentopexy was done and the hernia repaired.

Subsequent to the operation ascites recurred frequently, necessitating repeated paracenteses. He lost weight, gradually weakened and died March 14, 1938, about six months after admission. Prior to death there were no unusual abdominal complaints and no fever.

The clinical diagnoses were (1) atrophic cirrhosis of the liver and (2) chronic alcoholism.

Autopsy.—The skin of the anterior surface of the legs presented a small amount of brown mottling. The abdominal cavity was partly filled with turbid greenish fluid, which was more abundant in the artificial upper abdominal division made by the omentopexy. The parietal peritoneum was dark red and thickened. Friable fibrinous exudate covered the organs above the site of the omentopexy. Lying in the anterior wall of the duodenum at the pylorus was a crateriform ulcer which had perforated.

The liver, which weighed 1,575 Gm., showed beneath the fibrinous exudate a finely to coarsely nodular surface and was strikingly yellowish brown. The consistency was greatly increased, and the surface of the cut section was studded with yellowish brown nodules which measured from 2 to 4 mm. in diameter and were surrounded by much less pigmented copious stroma. The pancreas weighed 160 Gm. It had the same yellowish brown color as the liver, and its consistency was firm. Sections of the liver and pancreas when wet with potassium ferrocyanide and dilute hydrochloric acid gave the brilliant blue-green color of hemosiderin.

The thyroid was similarly but less deeply pigmented. No other organs were pigmented. The lungs showed some edema and congestion. The other organs showed no changes of note.

Microscopic Examination.—The liver exhibited marked thickening of the periportal stroma made up of proliferating fibroblasts, collagen, capillaries and proliferating bile ducts. Enveloped by this hyperplastic stroma were nodules of liver cords without central veins. Practically all the liver cord cells were laden with more or less centrally arranged granular brown pigment which reacted positively for hemosiderin. Much similar pigment was seen in Kupffer cells. In the stroma it was observed in macrophages, fibroblasts and duct epithelium or as extracellular granules.

The pancreas showed fine perilobular and peri-insular thickening of moderately well collagenized connective tissue. The islands of Langerhans, which were generally large and numerous, presented an increase in interstitial connective tissue. A few were compressed by scar tissue. Much finely granular pigment was deposited in the stroma, in the islands and in the acinar epithelium.

Large quantities of hemosiderin were observed also in a chronically inflamed pancreatic lymph node. The acinar epithelium of the thyroid gland was also heavily laden with the pigment.

The stratum glomerulosum of the adrenal cortex exhibited a small quantity of pigment in its stroma. Small granules of hemosiderin were seen in cardiac muscle fibers in the epithelium lining the convoluted tubules of the kidney. The spleen exhibited the thick-walled gaping sinuses and increased pulp stroma of chronic passive congestion. Much hemosiderin was found beneath the capsule and in the pulp.

The testicle showed no hemosiderin. A section of skin taken from the anterior surface of a leg exhibited considerable hemosiderin, deposited chiefly about sweat glands and small blood vessels of the corium.

Histologic examination indicated a chronic duodenal ulcer and an acute peritonitis which was probably of several days' duration.

COMMENT

This case of hemochromatosis with portal cirrhosis and ascites was terminated prematurely by the perforating duodenal ulcer. The classic triad of cirrhosis, diabetes and bronzing of the skin was not fully developed. Impaired dextrose metabolism was suggested by the slight trace of sugar found at the admission urinalysis and the history of alleged diabetes. Pigmentation of the skin, which was limited to the mottling of the anterior surface of the legs, was scarcely enough to arouse suspicion.

It is of interest that there were no signs or symptoms indicative of a chronic duodenal ulcer or of its perforation and resultant peritonitis.

MARKED EOSINOPHILIA IN HODGKIN'S DISEASE

RALPH H. MAJOR, M.D.
AND
LEE H. LEGER, M.D.
KANSAS CITY

Eosinophilia is not a rare phenomenon, but patients with an eosinophil count exceeding 90 per cent are very uncommon. In the following case the differential count showed an eosinophil count which was constantly above 90 per cent and on several occasions as high as 98 and 99 per cent.

REPORT OF CASE

History.—R. C., a Negro aged 21, referred by Dr. Robert Moore of Lansing, Kan., admitted to the University of Kansas Hospitals April 14, 1938, complained of fever, sweats, weakness and loss of weight. The family history was essentially negative. There was no history of tuberculosis, carcinoma, diabetes, epilepsy or heart disease. The personal history was essentially negative.

In 1936 the patient was in an automobile accident and injured his right biceps. Nov. 20, 1937, he was operated on for repair of the injury and during the month of December suffered from what he described as "pleurisy pains" in the left side of the chest. Shortly afterward he began to have fever, which continued intermittently until his death. The latter part of January he began to have a dry cough and soon afterward swollen glands developed in the left side of the neck. One of these glands was removed for diagnosis April 2, 1938, and was sent to the University of Kansas Pathological Laboratory for diagnosis. The diagnosis was "Hodgkin's sarcoma of lymph gland, acute

1. Binford, C. H.; Lawrence, R. L., and Wollenweber, H. L.: Hemochromatosis with Primary Carcinoma of the Liver, Arch. Path. 25: 527 (April) 1938.
2. Sheldon, J. H.: Haemochromatosis, New York, Oxford University Press, 1935.

From the Department of Internal Medicine of the University of Kansas School of Medicine.

lymphadenitis." The patient, since the beginning of his illness, had lost 75 pounds (34 Kg.).

Examination.—The patient was very poorly nourished. The nails and mucous membranes were very pale. The cervical, supraclavicular and occipital lymph glands were palpable and somewhat enlarged. There was a draining sinus in the left side of the neck. The chest showed an impairment of the percussion note on the left side and numerous musical rales. The heart was normal; the pulse rate was 96 and the blood pressure 135 systolic and 85 diastolic. Examination of the abdomen revealed the liver just below the costal margin; the spleen was not palpable.

Urinalysis showed a trace of albumin and was otherwise negative. The blood on admission showed red blood cells 4,300,000, white blood cells 61,000, hemoglobin content 71 per cent (11 Gm. per hundred cubic centimeters), blood platelets 210,000, color index 0.82, volume index 0.96. The differential count showed polymorphonuclear leukocytes 2 per cent, lymphocytes 3 per cent, eosinophils 93 per cent, monocytes 1 per cent, myelocytes 0, metamyelocytes 1 per cent, lymphoblasts 0. A filament count on the eosinophils showed filament forms 76, nonfilament forms 17. The results of a series of blood counts are shown in the accompanying table.

Blood Counts

Date	White Blood Cells	Polymorphonuclears	Filament Forms	Nonfilament Forms	Lymphocytes	Eosinophils
4/14/38	61,000	4	1	3	3	93
4/15/38	56,500	2	2	0	4	93
4/16/38	60,000	2	2	0	3	95
4/18/38	64,000	7	4	3	..	90
4/19/38	74,000	3	3	0	..	94
4/20/38	85,000	0	..	..	3	97
4/21/38	120,000	4	1	3	2	94
4/22/38	169,000	4	2	2	1	95
4/23/38	126,000	7	6	1	2	91
4/25/38	147,000	6	2	4	1	93
4/26/38	119,000	4	2	2	1	95
4/27/38	118,000	7	6	1	3	90
4/29/38	112,000	2	1	1	..	91
4/30/38	115,000	4	2	2	5	91
5/ 2/38	93,000	..	..	..	..	99
5/ 3/38	91,000	..	..	..	1	99
5/ 4/38	86,000	1	0	1	2	97
5/ 5/38	74,000	..	..	..	1	99
5/ 6/38	59,000	..	..	..	1	99
5/ 7/38	55,000	1	..	..	1	98
5/ 9/38	50,000	1	..	..	1	98
5/10/38	57,500	7	6	1	1	92
5/11/38	37,500	10	6	4	3	87

The patient continued to have profuse sweats and daily elevations of temperature; he gradually grew weaker and died May 12. An autopsy was performed the same day by Dr. R. A. Richeson. The anatomic diagnosis was abdominal Hodgkin's sarcoma with metastases to the parietal pleura, dura mater and retroperitoneal lymph nodes; acute and chronic lymphadenitis; hyperplastic bone marrow; acute dilatation of the heart, bilateral hydrothorax, hydropericardium and hydroperitoneum.

COMMENT

The question arose at first as to whether this patient was suffering from eosinophilic leukemia. Against this diagnosis were the absence of myelocytes, the absence of an enlarged spleen and the pathologic report that the excised lymph gland under the microcope showed Hodgkin's disease. The high white blood cell count at first glance would seem to be against the diagnosis of Hodgkin's disease, but examination of the literature shows that counts have been recorded in which the white blood count was as high as 75,000, and in one case reported by Stewart [1] the white blood count was 130,000 and the percentage of eosinophils varied from 72 to 90.

1. Stewart, S. G.: Eosinophilic Hyperleukocytosis in Hodgkin's Disease with Familial Eosinophilic Diathesis, Arch. Int. Med. 44: 772-783 (Nov.) 1929.

The high percentage of eosinophils in Hodgkin's disease seems to be, however, the exception. Roth and Watkins [2] in their study of forty cases of Hodgkin's disease found the eosinophil count within normal limits. Sears [3] reports a case in which there was an eosinophil count as high as 57 per cent and has collected from the literature a series of fourteen cases in which the eosinophil counts were 44, 68, 68, 36, 26, from 65 to 80, 68, 33, 16, 85, 60, 40, from 72 to 90 per cent, the last count being that of Stewart, to which reference has been made.

In our case it is noteworthy that there was only one count recorded below 90 per cent, and in four counts the percentage of eosinophils was 99.

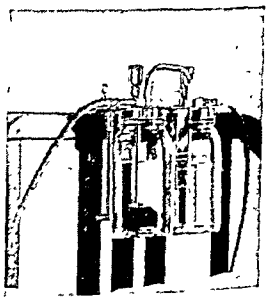
Council on Physical Therapy



THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary.

UNIVERSITY OXYGEN HUMIDIFIER ACCEPTABLE

Manufacturer: Scanlon-Morris Company, Madison, Wis.

The University Oxygen Humidifier is designed for use in the nasal catheter method of oxygen therapy. It is similar to the Wisconsin Oxygen Humidifier previously accepted (THE JOURNAL, June 3, 1939, p. 2276) by the Council except that this unit has only two glass jars, the third, a trap jar, being omitted, and that it can be mounted on the back of the bed. One bottle serves to humidify the oxygen and the other to measure the rate of oxygen flow. Both are mounted on a chromium-plated brass frame with carrying handle and rubber-covered adjustable arms for attachment to the head of the bed. Equipment includes rubber tubing to connect the oxygen cylinder and the nasal catheter with the bottles, a glass adapter to connect the catheter with the tubing, and four nasal catheters with perforated tips. Quart size mason jars are used to permit quick replacement in case of breakage.

University Oxygen Humidifier.

A special carbon filter is installed in the humidifier through which oxygen passing from the oxygen cylinder is broken into the fine bubbles for the purpose of saturation with water. The flow-gage chamber indicates approximately the flow of oxygen in liters per minute. Both chambers should be kept partially filled with water by means of filling cups. It is possible to adjust the rate of flow through the humidifier from 1 to 10 liters per minute.

The manufacturer submitted the following data in support of the efficiency and accuracy of the unit: In humidity tests run at a rate of 6 liters flow per minute, the usual rate employed, approximately 93 per cent relative humidity was found in the gas leaving the unit. This was cut down somewhat by air dilution in the pharynx. The advantage of this unit over the three-jar type is solely that of convenience, in that it lends itself to hanging on the head of the bed, is out of the way, and is easily seen by nurses for checking.

The unit was examined by a qualified investigator, who confirmed the claims of the manufacturer and found the apparatus adequate in humidification of oxygen.

From a review of the data, however, the Council concluded that there are faults in the fundamental principles of this type of nasal catheter treatment. Even though the flowmeter may indicate a therapeutic rate of flow, all too frequently more than half of this amount is lost to the patient. The hazard of break-

age of glass above the patient as well as the decay of rubber gaskets in the presence of oxygen is also to be considered.

In view of the foregoing report, in which the claims of the manufacturer are substantiated, the Council on Physical Therapy voted to include the University Oxygen Humidifier in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

PAUL NICHOLAS LEECH, Secretary.

ACCEPTANCE OF BRANDS OF SULFAPYRIDINE

Three brands of sulfapyridine were submitted to the Council, respectively, by the Calco Chemical Co., Inc., Lederle Laboratories, Inc., and Merck & Co., Inc. In the consideration of these brands there arose the question of proprietary names. The firms were advised as follows:

> The Council voted to accept products labeled "Sulfapyridine" with the understanding that a firm may apply for recognition of the right to a proprietary name at a later date. However, until such time as satisfactory evidence has been submitted to warrant the Council's recognition of a proprietary name for sulfapyridine of one of the firms, the name "Sulfapyridine" shall be used; of course it is understood that the proprietary name shall be of an acceptable type.

Merck and Lederle were also advised that they could use the subtitle "Introduced as Dagenan—M & B 693" on labels and in advertising for a period of one year, after which it must be removed unless in the meantime the right to a proprietary name has been established; that the name must not only be acceptable by rights of proprietorship but that the name itself must be of an acceptable type.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

SULFAPYRIDINE (See THE JOURNAL, May 6, 1939, p. 1831).

Sulfapyridine-Calco.—A brand of sulfapyridine-N. N. R.

Manufactured by The Calco Chemical Co., Inc., Bound Brook, N. J. U. S. patent applied for. No U. S. trademark.

Tablets Sulfapyridine-Calco, 0.5 Gm. (7.7 grains).

Sulfapyridine-Lederle.—A brand of sulfapyridine-N. N. R.

Manufactured by Lederle Laboratories, Inc., Pearl River, N. Y., by license of May & Baker, Ltd., Dagenham, England. U. S. patent applied for. No U. S. trademark.

Tablets Sulfapyridine-Lederle, 0.5 Gm. (7.7 grains).

Sulfapyridine-Merck.—A brand of sulfapyridine-N. N. R.

Manufactured by Merck & Co., Inc., Rahway, N. J., by license of May & Baker, Ltd., Dagenham, England. U. S. patent applied for. No U. S. trademark for sulfapyridine.

Tablets Sulfapyridine-Merck, 0.5 Gm. (7.7 grains).

SULFANILAMIDE (See New and Nonofficial Remedies, 1938, p. 450; THE JOURNAL, Feb. 25, 1939, p. 733).

Tablets Sulfanilamide, 5 grains-The Upjohn Company.

Prepared by The Upjohn Company, Kalamazoo, Mich. No U. S. patent or trademark.

Tablets Sulfanilamide, 7½ grains-The Upjohn Company.

Prepared by The Upjohn Company, Kalamazoo, Mich. No U. S. patent or trademark.

CORRECTION

Iodobismitol with Saligenin-Cutter.—In the published description of the product in THE JOURNAL, June 3, page 2279, the phrase "and from 0.318 to 0.258 Gm. of sodium iodide" should read "and from 0.218 to 0.258 Gm. of sodium iodide."

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

CELLU BRAND PEACH JUICE

Distributor.—Chicago Dietetic Supply House, Inc., Chicago.

Description.—Canned peach juice packed without added sugar.

Manufacture.—Choice yellow cling peaches on which no toxic spray material has been used and which are too soft for the regular pack as halves are selected, pitted, peeled, trimmed to remove blemishes, preheated, crushed and pressed through special mesh cloths in a hydraulic press. The juice, containing some of the insoluble solids which are left in to lend color, is filled into cans and heat processed.

Analysis (submitted by distributor).—Moisture 88.7%, total solids 11.3%, ash 0.4%, fat (ether extract) 0.4%, protein (N × 6.25) 0.4%, crude fiber 0.04%, carbohydrates other than crude fiber (by difference) 10.1%, invert sugar 4.58%, sucrose 4.62%.

Calories.—0.5 per gram; 14 per ounce.

V-B-W (VITAMIN B_1 WAFER)

Manufacturer.—Hilker & Bletsch Company, Cincinnati.

Description and Use.—Packaged cookies prepared from wheat flour, sucrose, hydrogenated shortening, eggs, dextrose, powdered skimmed milk, salt, baking powder, flavoring, with added thiamin chloride to furnish about 100 international units of vitamin B_1 per wafer. Intended as a special purpose food providing vitamin B_1 in convenient form.

Manufacture.—Crystalline vitamin B_1 (thiamin chloride) is mixed with a small amount of sugar and in turn is thoroughly mixed (creamed) with definite proportions of sugar, hydrogenated shortening, dextrose, powdered skimmed milk, salt and flavor. The eggs are thoroughly worked in, water is added, and the flour and baking powder are worked in. The wafers are mechanically cut, placed on trays, and baked under conditions designed to maintain a standard vitamin B_1 content.

Analysis (submitted by manufacturer).—Moisture 2.3%, total solids 97.7%, ash 1.0%, sodium chloride 0.58%, fat (ether extract) 11.4%, protein (N × 6.25) 6.6%, crude fiber 0.12%, carbohydrates other than crude fiber (by difference) 78.6%, calcium (Ca) 0.079%, phosphorus (P) 0.039%.

Calories.—4.4 per gram; 125 per ounce; 15 per 3.41 gram wafer. Wafer count to the pound, about 133.

Vitamins.—Reports of biologic and chemical assay submitted by the manufacturer indicate that V-B-W (Vitamin B_1 Wafer) contains not less than 100 international units of vitamin B_1 in each wafer.

CELLU BRAND JUICE-PAK FRUIT COCKTAIL

Distributor.—The Chicago Dietetic Supply House, Inc., Chicago.

Description.—Canned mixture of diced peaches, pears, whole Thompson seedless grapes, diced pineapple and whole Royal Ann cherries packed in mixed juice.

Manufacture.—Canned Royal Ann cherries (packed in juice) are counted into the cans by hand. Fresh peaches, fresh pears and canned pineapple (packed in juice) are mechanically diced and automatically filled into cans along with whole, fresh Thompson seedless grapes. Juice from the cherry and pineapple stock and that pressed from fresh peaches and pears are blended and added. The cans are heated, sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 89.1%, total solids 10.9%, ash 0.3%, fat (ether extract) 0.3%, protein (N × 6.25) 0.4%, invert sugar 7.4%, sucrose 1.4%, crude fiber 0.4%, carbohydrates other than crude fiber (by difference) 9.5%.

Calories.—0.42 per gram; 12 per ounce.

SATURDAY, JUNE 24, 1939

THE INDEX NUMBER

In this issue of THE JOURNAL, which is the Index Number, it has been necessary to abbreviate some departments and to omit others entirely because of the scope of the index. It is recommended particularly that readers consult page 2648 of the index under the heading "American Medical Association." A survey of the material listed will indicate the vast scope of the activities of the Association at this time. It is in a sense a review of the work for the first six months of the year. Few people realize the information to be derived merely from turning the pages of an index one by one. For example, the relative amounts of material on page 2650 concerned with anaphylaxis and allergy and with androgens indicate the extraordinary development of interest in the latter subject during the period covered by this volume. No other medical periodical provides in a six months period the amount of information available through THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. It is with pardonable pride that we assert that the physician who wants to keep abreast of scientific, political, economic, social, literary or any other phases of medicine can do so by consistent, thorough reading of this publication.

THE RELIEF OF PAIN IN CHILDBIRTH

Ideal methods for relieving the pain of childbirth have been the goal of obstetricians since ancient times. Inscriptions and drawings left by early Egyptians [1] indicate that they tried unsuccessfully. Less than a century has elapsed since Sir James Y. Simpson of Edinburgh first used an anesthetic, a few drops of chloroform, for this purpose. In 1880 Klikowitsch introduced the use of nitrous oxide, a method popularized by J. Clarence Webster, Frank Lynch and Carl H. Davis of Chicago, and by Guedel of Indianapolis. Some years before, Steinbuchel, and Gauss of Germany, had suggested the use of scopolamine and morphine for alleviating labor pain, a method which under the name "dammerschlaf," or "twilight sleep," for a time was immensely popular. As originally employed, this method was soon discarded because of uncertain results, with an increase in maternal and fetal mortality. A modification of this method, however, is still widely used. In 1913 Wallace of New York experimented with ether-oil rectal anesthesia, and his results later were applied clinically in the Lying-In Hospital by Davis and by Gwathmey. The barbiturates then came into use for the relief of labor pains. Hirst and his associates reported their results with sodium amytal in thirty cases in 1929, in which year Vogt and Kautz reported on the obstetric use of pernocton. In 1933 Whitfield published his results in 744 cases in which he used several of the foregoing methods. Obviously many different methods are now employed in various parts of this country for the relief of labor pains. In 1936 Insulander [2] came to the United States from Sweden to study the developments. Twenty well known hospitals in widely separated cities were visited and it was found that in every one of these hospitals a different technic was used. If the same drugs were used, the dose or method of application differed. It was difficult to evaluate the numerous methods because the obstetrics observed in America was fundamentally different from that in general use in Sweden. The impression obtained was that in many places here the plan was to favor intervention in labor as much as possible, whereas in Sweden they favor as little intervention in labor as possible. In some hospitals the deliveries were all operative and the physician who could show only 25 per cent operative deliveries was considered too conservative. Insulander found that the obstetricians themselves thought that the drugs used decidedly caused an increase in the number of artificial or operative deliveries. In Germany it was found that analgesics at childbirth were sparsely used, as they are also in Sweden. Indeed, in parts of the United States there is a definite reaction against their widespread use.

Nevertheless, an increasing number of physicians in the United States are using obstetric amnesia or analgesia. To determine the trend as to methods, Bushnell obtained the opinions of seventy-three obstetricians. The concept of polypharmacy permeated the replies. Many obstetricians use not only a hypnotic but also an amnesic and some include an anesthetic. Pentobarbital sodium either alone or in association with other drugs seemed to have the greatest number of advocates in this representative group. Rectal ether-oil is employed either in the usual modified Gwathmey technic or as an inhibitor of the barbiturate excitements. Ethylene and oxygen are used by many for analgesia and anesthesia, as is nitrous oxide and oxygen. Paraldehyde, alone or in combination, has a large number of adherents. Local anesthesia was used by seven of the obstetricians. Cyclopropane was recommended by

1. Bushnell, Lowell F.: The Trend of Obstetrical Amnesia and Analgesia, Surg., Gynec., & Obst. 67: 655 (Aug.) 1938.

2. Insulander, Margit: Relief of Pains in Childbirth, Acta obst. et gynec. Scandinav. 18: 179. 1938.

one, three used spinal anesthesia, one clinic uses heroin and even chloroform is still used.

Though the barbiturates are popular, experience has shown that they are far more than simple hypnotics. Indeed, physicians should not attempt to use any drug for analgesia and amnesia without full understanding of its properties. Irving, Berman and Nelson [3] a few years ago made a clinical evaluation of eight methods in use at that time. Pentobarbital sodium and scopolamine gave them the best results. Among 860 patients, 86 per cent had absolute loss of memory of labor. There were no failures, and no stillbirths due to the effects of the drugs.

Bushnell outlines the routine in use by many advocates of this drug. The patient should eat frequent small meals when labor is imminent and abstain from eating solid food after regular pains have begun. Indications for the initial dose varies with obstetricians. The dose commonly used is between 4½ and 9 grains (0.3 and 0.6 Gm.), depending on the patient's weight. It is accompanied by a single dose of scopolamine ranging from 1/200 to 1/100 grain (0.00032 to 0.00065 Gm.). The barbiturate is usually given by mouth and the scopolamine subcutaneously; in nauseated patients it may be given rectally. The patient should be under the constant care of an experienced attendant who does not disturb or restrain her. Restlessness between pains is the usual indication for additional dosage, usually by rectal insertion of a perforated capsule. Most obstetricians agree that this method is contraindicated in patients who are poor anesthetic risks, who have acute liver damage or heart disease and who show any pulmonary or upper respiratory pathologic conditions. The majority believe that the method is contraindicated in home obstetrics. Whitfield [4] has recently described a method of giving paraldehyde in capsules in combination with pentobarbital sodium and morphine which, he says, is applicable to home as well as to hospital obstetrics.

Certain objections have been offered to the use of obstetric amnesia and analgesia. The objectors condemn the prophylactic use of outlet forceps. All drugs, they say, reduce uterine contractions and interfere with the normal uterine function. The change in the uterine activity predisposes to hemorrhage. All analgesics have a depressing effect on the respiratory center of the fetus. Spontaneous delivery when easy is a preventive of birth trauma. Childbearing is an essential experience to a woman, which should not be changed from its normal course because of the possible danger of her own personality.

The ideal drug or combination of drugs has not yet been discovered. Perhaps in the hands of masters all of the methods mentioned are essentially safe for both mother and baby. The skilled obstetrician, at least, has the opportunity to choose the particular technic best suited to each case. The enthusiasm and great interest in this problem offer hope for the development of still better methods of relieving the pain of childbirth.

THE AGING PROCESS

The life expectancy at birth in such countries as the Netherlands, Switzerland and New Zealand is slightly greater than that in the United States. In several of our Northern states, however, the figures reflect a better experience than that recorded in most foreign countries. The explanation appears to lie in the much lower life expectancy among Negroes, a fact which tends to distort the conclusions which might be drawn from examination of only the comparative gross statistics. There is no doubt, therefore, that the life expectancy of the white population of the continental United States is as long as or longer than that of any other country in the world, although that of Negroes is disturbingly out of proportion.

The control of the communicable diseases has been the most important factor in increasing average longevity; in fact, except for tuberculosis and for pneumonia, all the other infections have been almost eliminated as factors of importance so far as the death rate is concerned. For tuberculosis there has been a decrease in the average death rate since the decade from 1856 to 1865 of more than 90 per cent. With better understanding of the epidemiology and the social and individual factors involved in the spread of this disease, tuberculosis as a cause of death will probably recede still further in importance. If this occurs, as may be reasonably anticipated, ordinary foresight should lead some of the sanatoriums now devoted to the care of the tuberculous to consider their probable functions at some later time when their facilities may not be completely occupied by patients with this disease.

For pneumonia, the record has not been as good as for tuberculosis. From an average death rate of 107 per hundred thousand of population in 1856-1865 the decrease is only to 96 per hundred thousand of population in 1936. Today, however, with increased knowledge of etiology, of epidemiology, of diagnosis and especially of newer forms of treatment, a relatively short span of years should remove pneumonia from its exalted position as third among the causes of death.

Highly unsatisfactory has been the experience with the large number of accidents which maim or destroy human life in the home, on the highway or in the factory. According to insurance statistics, the amazing number of 104,000 persons died accidentally in the United States in 1937. Since accidents rate high among the causes of death, their material reduction would further favorably affect average longevity.

The two metabolic diseases most likely to interfere with aging are obesity and diabetes. These disorders may be partially classed as metabolic and associated

with the aging process but are also influenced by hereditary and nutritional factors. Since this is the case, the fact that the nutritional requirements of older persons are less per kilogram of body weight deserves constant reiteration. Important also are the foods, particularly such proteins as are contained in liver, and the vitamin B complex and iron.

With the decline of the birth rate and the coincidental increase in the number of individuals living to mature and later years, the character of the national population is being slightly modified. As a result, Piersol and Bortz [1] feel that the temper of the people is bound to assert itself in certain important changes which will extend into all the various phases of social, economic, political and professional life. A more mature national mind, they believe, should have a steadying influence on the life of a nation. Already many industries have modified their views on workers in the older years. It is beginning to be appreciated that those over 40 often bring to an industry certain advantages more than compensating for any alleged fault associated with the older years. Since at present 260 of every thousand persons living in the United States are 40 years old or over and since it is estimated that 36 per cent of the population will be between 40 and 65 years old by 1960, the problem of industrial adjustment to this development is already here.

Current Comment

GENESIS OF APPENDICITIS

From sixteen to eighteen thousand persons continue to die each year in the United States from appendicitis. Through the years from ages 5 to 19 the disease ranks as the second to the fifth most frequent cause of death. In the ensuing years, whereas its toll of life remains largely the same for several decades, appendicitis wanes in significance because other more frequent causes of death appear. Incidentally the mortality from appendicitis is higher by occupation among physicians and surgeons than among the population at large. Wangensteen [1] has done much to elucidate the problem of causation. Gerlach's valve, which is a fold overlying the appendical orifice, is believed to interfere with or preclude the filling of the lumen of the appendix. Its absence, as frequently occurs, would facilitate obstruction of the appendix and consequent inflammatory reaction. In a series of ingenious observations on the lumen of the appendix, Wangensteen found that human appendixes which were not obstructed had a luminal capacity at 20 cm. of water pressure of only 0.23 cc.; at 60 cm. pressure the highest luminal capacity was 0.7 cc. When the attempt was made to break the normal appendix by increasing the pressure, it was found that none of three appendixes directly following excision could be ruptured by pressures as high as 2,400 cm. of water. Gangrenous, unruptured appendixes, however, were found to break at extremely low pressures, one at 20 cm. of water and another at 70 cm. Apparently, therefore, the presence of an inflammatory reaction in the appendical wall greatly decreases strength. Further experimental evidence indicated that the vermiform appendage of the rabbit will perforate quite regularly after about ten to fourteen hours of obstruction. All of the varieties of appendicitis recognized by pathologists may be produced by luminal obstruction in animals whose vermiform appendage possesses the capacity to secrete fluid as does that of man. Fecaliths and swelling of lymphoid tissue are probably the most frequent causes of appendical obstruction in man. Kinks, bands, position (retrocecal) and stenoses may also cause obstruction. The matter of "geography, diet and culture" as related to the origins of appendicitis is thus demonstrated to be a myth. Appendicitis may be clearly recognized as a problem of public health. Better understanding of the functional behavior of the vermiform appendix should bring physicians as well as other patients with appendical colic to the operating table much earlier.

EFFECT OF ACIDIFIED CANDIES ON TEETH

Freshly extracted teeth were used by West and Judy [1] in experiments designed to test the destructive action of solutions made from acidified candies on the dental enamel. The teeth were mounted singly in rubber stoppers by embedding the roots in beeswax followed by a coat of acid proof paint. Only sound enamel was exposed. The teeth were then subjected to solutions of varied strength of acidified candies in water, these solutions showing high acid reactions with p_H values ranging from 2.5 for the strong solutions to 5.4 in some of the 20 per cent solutions in normal saliva. The destruction of enamel was greater the lower the p_H of the solution and the longer the period of exposure. It was pointed out in the discussion that, when a person places a piece of ordinary acidified candy in his mouth and allows it to dissolve slowly against his teeth, the concentration of the solution at the surface of the candy and in contact with the tooth enamel will be high with a probable p_H of from 3 to 4. If repeated at frequent intervals, the experimental data would indicate that serious decalcification is likely to result. Although the buffering action of the saliva in the mouth, where it is being continually secreted, is undoubtedly more efficient against acidified candies than in the experiments reported, the teeth treated in the experiments under conditions that lead to solution of tooth enamel showed a chalky insoluble layer on the surface which could be easily scraped off. The calcium phosphorus ratio in this material was high, owing to the exchange of citrate ion of the solution for the phosphate ion of the enamel. These investigators, therefore, are of the opinion that this phenomenon of ionic exchange between tooth enamel and acidic groups of various foods may be an important factor in the general process of tooth destruction throughout the years of tooth life.

ORGANIZATION SECTION

ABSTRACT OF HEARINGS ON THE WAGNER HEALTH BILL

(Continued from page 2539)

(Additional hearings before the Subcommittee of the Committee on Education and Labor.)

STATEMENT BY DR. THOMAS PARRAN

Dr. Thomas Parran, Surgeon General of the United States Public Health Service, stated that the Wagner Health Act is a logical outgrowth of the Social Security Act and the most comprehensive approach ever made to the diverse and serious problems of health and medical care for the nation. He felt that the bill very wisely proposes the grant in aid system, saying that "this is such a well established part of our governmental structure that it seems unnecessary for me to defend the principle." He then discussed the health condition of the nation, pointing out that death rates are not a measure of national fitness; neither do death rates give an indication of the economic burden which disability creates among the low income groups in our population. He said that less than one third of the counties and even a smaller proportion of the cities employ full-time professional health officers. Concerning the distribution of physicians in hospitals he said:

We have in this country some 160,000 physicians in active practice—an average of one physician to 807 persons. But in certain of the predominantly rural states—the Dakotas, Mississippi, North and South Carolina—each physician serves an average of 1,300 persons or more. In Kentucky, one physician serves an average of 1,106 persons in the state as a whole, but in nine counties of the state the average population per physician is 3,000 or more. The situation in Kentucky is not an isolated example; internal variation of a similar nature may be observed in the predominantly urban states. New York State is, on the average, well supplied with physicians; yet a few years ago in its largest cities there was an average of one physician to 535 persons, while in its small towns and villages the ratio was one physician to almost 1,000 persons. These figures illustrate a general trend—the tendency of physicians to concentrate in the large urban centers, which, through their hospitals and clinics, offer opportunity for the application of modern medical technic.

Your committee has heard very divergent points of view concerning the hospital situation in the country. It has been stated, for example, that an average of 195,674 beds in existing institutions are empty. I would point out, first, that no hospital can operate at 100 per cent capacity. From 80 to 85 per cent bed occupancy is considered full capacity for general hospitals because of the necessary division of wards and sections by sex, disease, and so on. For example, a temporary surplus of beds in the obstetric ward cannot be used for the care of measles or scarlet fever. Medical and surgical conditions cannot be mixed. In some areas the color division further complicates the problem.

The most determining point, however, is the lack of ability of patients to pay for hospital care. The data show that the public hospitals, which by and large are free, are more than filled to capacity, while private rooms in voluntary and proprietary hospitals remain empty. There is an anomalous situation in the fact that in many areas which have the lowest number of hospital beds per capita there is the highest percentage of unused beds. Lack of money, not lack of patients, keeps them empty.

Even a small subsidy to free care of patients in hospitals is of great assistance in securing medical care for the poor. Some of you may know that in North and South Carolina the Duke Endowment started some years ago to provide a subsidy of $1 a day for each free patient in approved hospitals of those states. When this work was started only nine patients in every hundred being treated in the hospitals of the Carolinas were free patients. As a result of this subsidy of $1, today the percentage of free care has risen to 45, a fivefold increase in the number of needy patients who have been given needed hospital treatment. The fivefold increase in free patients is made up largely of those who previously went without care simply because the hospital could not afford to admit them.

Senator Murray:—How is that subsidy provided that you described there?

Dr. Parran:—It is provided by the Duke Endowment, whereby any hospital which meets standards which they have prescribed, reasonable standards as to records and physical conditions in the hospitals—

Senator Murray (interposing):—I did not catch the word "Duke" at first. I thought it was some other organization.

Dr. Parran:—It is the Duke Endowment.

The bill under consideration proposes to use public monies, federal, state and local, to pay for the care of needy patients in existing public and private hospitals.

Senator Murray:—Was there not an understanding that it would not apply to the private hospitals?

Dr. Parran:—Quite the contrary, Mr. Chairman. The use of public monies is contemplated under this act, and particularly under titles I, III and VI, to pay for the care of needy patients in existing public and private hospitals. Under title XII it was not contemplated that public monies would be used in the construction—to assist in the construction of privately owned hospital facilities. It is perhaps on that point that the misunderstanding has arisen.

Under this bill, every available bed would be utilized before additional hospitals would be built. Even when this is done, however, there still remains a need in many areas for additional beds. There are 1,338 counties containing about 17 million people in which there is no registered hospital. Obviously each of these counties does not need a hospital. We have estimated, however, that we do need about 500 rural hospitals. Many of these would replace present tumble-down shacks. As a matter of fact, the experience of the Commonwealth Fund in aiding the construction of rural hospitals has shown that, of some 1,300 or 1,400 hospitals which they have aided, in every instance but one, one or more existing so-called hospitals has been closed up—fire traps frequently, very inadequate facilities, and totally inadequate to meeting the needs of the community.

Senator Murray:—Doctor, would not a great many of these so-called fire traps that you have mentioned, would the communities not be glad to rebuild their hospitals or build new hospitals if they have the financial aid to do it?

Dr. Parran:—Most of them would, yes, sir, without a doubt, and that has been the experience of the Commonwealth Fund in giving aid to communities which have asked for assistance.

Senator Ellender:—Doctor, with respect to the assistance to be given to needy patients, there has been quite a lot of testimony to the effect that this bill does not make the difference between the indigent and those who could afford to pay. Can you point out in the bill wherein that would apply, that no distinction is made between the needy and the indigent?

Dr. Parran:—Senator Wagner has emphasized that very point, Senator Ellender, on a number of occasions. The bill does use the words "particularly in rural areas and among needy persons." The bill contemplates primarily the giving of aid for the medically needy, but then the question arises How is it possible in any federal legislation to define the medically needy? Very wisely that definition is left to the state. Moreover, under title XIII as now written, it would be possible for a state if it wished to pass appropriate state laws and tax itself, or to provide free insurance contributions, to give medical care to persons who are above what we call the marginal level. The bill does not prohibit it; it does not, however, coerce the states to do it.

A mere statement of the number of hospitals does not indicate the adequacy of hospital facilities. This is well illustrated by the general hospital situation in the states of the South in comparison with those of the Northeast. Each section contains about 30 per cent of the total population of the country and each is served by approximately the same number of local general hospitals, 1,217 in the Northeast, 1,177 in the South. But the bed accommodations in these hospitals of the Northeastern states total some 157,000, in the South only 67,000.

[Dr. Parran then discussed distribution of hospitals for the tuberculous and for the mentally diseased, stating that twenty-six states have less than one bed per annual death from tuberculosis. For the mentally diseased the state with the highest ratio of beds has 6.88 beds in mental institutions per thousand persons, whereas the lowest ranking state has 1.96 beds per thousand of population. He asserted that 130,000 new beds would be required to bring the remaining states up to the standard of 4.8 which one fourth of the states now meet or exceed. He then continued:]

In the case of local general hospitals the number of available beds varies among the states from 1.3 to 5.5 per thousand of

population. Professional judgment indicates that an average of 4.5 beds per thousand must be maintained to provide adequate facilities of this type. It is proposed that the states falling below this average should be aided in building additional hospitals when needed by provision of state and local funds to match the federal assistance. Only three states at present exceed this standard, and it is estimated that 180,000 additional beds in general hospitals will be required to bring all states up to the accepted standard of adequacy. I think it would be well to point out also that these estimates were based on a ten-year program of construction, during which the population inevitably will grow somewhat, and moreover it obviously rests with the Congress from year to year to make such appropriations as are shown to be needed by the actual shortage of facilities in the various states. It may be that there is an excess of hospital beds in some states or some parts of states. The difficulty is, however, that we may not move the beds and it is impracticable to move the patients over long distances.

Two generations ago the only function of a hospital was to serve as a place where the sick poor could go to die. With the development of modern medicine they have become a vital force in health conservation. Decade by decade utilization of hospitals has increased. This trend is apt to continue and it will be intensified by the increasing average age of the population, since older people on the average suffer more sickness.

Senator Taft:—Doctor, may I interrupt you, because I have to go to the Appropriations Committee. On the question, the general question as to whether the bill permits the use of money to pay for beds in private hospitals, you would be in favor of having the bill permit that?

Dr. Parran:—The bill very specifically does permit the payment of a per diem or some other basis for care of patients equally in private voluntary and religious hospitals as it does in public hospitals.

Senator Taft:—We can settle about the provision of the bill later, but you are in favor of that principle?

Dr. Parran:—Yes, I am. But the bill does not provide for public monies to aid in the construction of privately owned facilities.

We have had much discussion of the number of people in the country that need medical care. The statement of the committee has been misinterpreted. There are about 40 million persons in this country who are in families with a total annual family income of less than $800, income derived from earnings and relief. I quote this estimate from the report of the Interdepartmental Committee. It was based on the national distribution of consumer incomes and records of recipients of relief.

The committee has defined this group of 40 million persons as the "medically needy." Even on casual consideration, it is evident that the standard of living permitted an average family of four persons on an annual income of $800 or less allows small margin, or none, to pay for good medical care. A family af this income level may be self sustaining in respect to the basic necessities; it is, however, needy in relation to its requirements for good medical care. The family on relief is also "medically needy"; but its indigence extends also to food, shelter and clothing. The 40 million persons to which the committee refers are in families such as these, receiving relief or supported by marginal incomes.

It is evident that this entire group of 40 million persons will not require medical care during a year. Almost one half of the group will experience no sickness. But the committee has estimated that about 8 million cases of illness disabling for a week or more will occur in these low income families, "and under the conditions prevailing in 1935, about 2 million of these cases will receive no medical care."

The committee's estimate of the proportion of unattended illnesses in this group of the medically needy was based on the results of the National Health Survey. This survey, made by the Public Health Service in the winter of *1936-1937*, employed the method of the house to house canvass, with which the service staff has had long experience. Its findings were analyzed under the direction of able statisticians with an acknowledged position of leadership in the field of morbidity statistics. The results of this survey are in general agreement with those observed in the peak years of prosperity by the committee on the costs of medical care under the chairmanship of former Secretary Wilbur. They are, furthermore, harmonious with the findings of the California Medical Association, which estimated a few years ago that 218,000 persons in the state of California alone were currently in need of medical care but not receiving it.

Medical care of this group differs as between large and small cities, and rural areas. Where relief has not broken down, public funds in the large cities meet some of the costs of medical care of the dependent for illness requiring treatment in hospitals. The ambulatory cases among the sick poor in metropolitan centers receive treatment in outpatient departments, which are, however, greatly overcrowded. But these organized facilities for care of the sick are less widely developed in small cities and rural areas, and governmental funds for their support are meager.

Private physicians provide much free care of the patients who come to them for treatment, but many patients receive no care because they are unwilling to ask for service when they cannot pay for it. This endeavor to balance a marginal budget by neglect of health is in part the cause of the high death and disability rates in this group. We have accepted responsibility in principle for public assistance to those otherwise unable to obtain food, shelter and clothing. We must accept also a community responsibility for medical care of those who cannot provide it out of their own resources.

This bill does not establish any system of compulsory health insurance nor does it require or coerce the states to do so. Very wisely, I think, it leaves a decision as to whether or not health insurance is to be adopted in any state to the state itself. It seems clear that one or another state may wish to adopt such a system, and it would seem quite illogical for the federal government to pass laws which would prevent a state from dealing with its medical problems in the way in which it wishes to do so.

Actual experience in some states will provide a sounder answer as to its usefulness than mere argument. In my opinion group payment of the costs of medical care, through taxation or insurance or both, for those groups of the population unable readily to pay the costs of such care for themselves, would be an important factor in any complete national health program.

Senator Ellender:—You would say that, under the bill, should a state desire to raise its pro rata amount of money so as to match with federal funds, that that could be done?

Dr. Parran:—Yes, sir.

Senator Ellender:—And you would not want that written into the bill that it cannot be done?

Dr. Parran:—I think it would be a very unwise policy for the federal government to interfere to that extent with the medical policies of the state which up to now have been reserved to the states, and which under this bill would still be reserved to the states.

[He then discussed work already done under the Social Security Act and the Venereal Disease Control Act, taking up next the subject of industrial hygiene.]

To reduce disability and premature death in our working population, to discover and correct physical impairments, forms an integral part of the entire health program. As an expression of this function, most of the states have organized industrial hygiene units; in twenty-eight states these units are under the direction of the state health department. In many instances these units are functioning with skeleton organizations. They need great expansion of their services. To accomplish this end is one of the important objectives of title VI of the bill. In those states in which industrial hygiene is administered by a department of labor or industrial commission, funds will be allotted for their use. It seems very unwise to complicate further the administrative provisions of the bill by creating a separate title and separate administration for industrial hygiene as has been suggested by witnesses before this committee.

If industrial hygiene needs a separate administration, why not school hygiene?

Why not dental hygiene? Why not mental hygiene?

I think one should realize that this whole effort to prevent and cure disease should be a unity effort. It is difficult to separate the interrelated parts. Public health is an individual and a family problem in the last analysis, and not a problem of school hygiene or industrial hygiene or mental hygiene or dental hygiene. I anticipate, if recommendations continue to be made before this committee for separate divisions, it may have the bill broken up into various absolutely unworkable sections. Every specialty in medicine might wish to have a separate title and separate administration, with utter chaos.

Senator Ellender:—We had two witnesses who testified, one from New York and one from Illinois, as I recall, and one from Michigan, too. The two from New York stated that industrial hygiene was operated under the labor department, and in Michigan under the health department. Is there any good reason for that? Is there any good reason why the state of New York should operate in that manner?

Dr. Parran:—It is a matter of historical development, Senator, and it would appear to me unwise for the federal government to attempt to dictate the practice in any particular state. It happened that New York was one of the first states to have a well developed department of labor, and the work started there. In the meantime, the—for instance, in Connecticut the labor department did not take up this subject and the health department did.

Senator Ellender:—In distributing funds for that purpose in those two states in contrast to Michigan, where it is under the health department, would you have the federal government or the state department to allocate the particular funds to its department, or would you let it be handled, let us say, under the health department of those states?

Dr. Parran:—I suggest that title VI of the bill stand as written with respect to the industrial hygiene services, because under the provisions as now written the New York State Department of Industrial Hygiene in the Department of Labor would be enabled to secure funds allotted by the federal Public Health Service.

Senator Ellender:—Direct?

Dr. Parran:—Direct, subject only to the requirement that funds allotted to some agency other than a state health agency need to be approved by the state agency.

Senator Ellender:—In other words, it could not be made even then in those states direct but had to be under the supervision, as it were, of the health department of that state?

Dr. Parran:—Supervision only to the extent of the approval of the plan, which I think on analysis you will agree is necessary, to have some balance. In New York State the school hygiene work is handled by the department of education; mental hygiene is handled by a separate department of the state government. If there were no control as to the balance between industrial hygiene, mental hygiene, school hygiene and general public health work, I think it is quite obvious that each of these unrelated problems would put in its budgets and plans, and each one would want all the money that is available and leave nothing for the other fellow.

Senator Ellender:—As a matter of fact, and I would say in any event, the budget would have to come from the state health division, would it not?

Dr. Parran:—It would be approved by the state health division.

Senator Ellender:—And it would have to be passed on finally by it, would it not, because, as I understand it, under this bill the allocation of funds would have to be done by and with the consent of the health officer of a state?

Dr. Parran:—Yes. Well, what is the alternative? Earmark so much money for the industrial hygiene, create a special title, and earmark so much for school hygiene, for milk sanitation, and so forth?

Senator Ellender:—I am just wondering why it is that it could not be more uniform. Why that duplication, because you are bound to have duplication, let us say in the states of New York and Illinois—there may be some others for all I know—wherein money for hygiene purposes is spent by one division under the labor department, and hygiene work under the health department for some other purposes.

Dr. Parran:—You are quite right; and yet we have seen a great diversity in state laws and practice not only in this field but in the tuberculosis. In some states, state tuberculosis hospitals are operated by a separate hospital board or a separate tuberculosis commission or a department of welfare or a department of health.

Senator Murray:—How many states have departments of industrial hygiene?

Dr. Parran:—Some thirty or thirty-one.

Senator Ellender:—Separate?

Dr. Parran:—They have divisions of industrial hygiene. In twenty-eight of them these divisions are operating under the department of health.

Senator Murray:—And in some of the states where they need it most, they have not got that department at all, isn't that true?

Dr. Parran:—If so, it is only a skeleton organization. These twenty-eight states have recently set up divisions of industrial hygiene and they have made a good start; they have gotten at least one or two trained persons in those divisions of industrial hygiene. They could be expanded, and their services could be expanded, and of course there would need to be new arrangements with the state department of labor which have factory inspection and that sort of thing.

Senator Ellender:—How many are there that have it under the jurisdiction of the labor department? I named two—New York and Illinois; do you know of any others?

Dr. Parran:—My best information is that there are three; one additional state besides those two.

The provisions of this bill would give responsibility to the Children's Bureau for medical care of children, to the Public Health Service for medical care of certain high cost illnesses (tuberculosis, cancer, pneumonia, venereal disease) and to the Social Security Board for medical care of persons other than children and for diseases other than those for which the Public Health Service is given responsibility. Rather than complicate further the administrative dispersion of responsibility among several unrelated agencies, I urge that the first objective of the bill be to coordinate federal health service.

We can never attain national health and fitness simply by money grants out of several federal pockets with no correlation between them, no joint planning, no uniform standards, and with diverse budgetary requirements, systems of reports, triplicating field staffs to deal with the states, and audit accounts.

Senator Ellender:—Well, doctor, in that connection, there was a witness, as I recall, who testified that quite a lot of this work was being done here in Washington under the federal government in the various departments of the government. Would you have any views on that? In other words, you talk about coordination; I wonder if we could not begin that at home here?

Dr. Parran:—I urge that as the first objective of the bill. As the head of one of the government bureaus, I feel somewhat reluctant to make a specific recommendation particularly in view of the reorganization act under which the President continues to have authority further to coordinate the health services of the government, and I may say that in my opinion, reorganization plan No. 1 was a fine step in the right direction in bringing health education and the social security board, among others, together.

Senator Ellender:—Have you studied this reorganization to find out whether or not the president could without legislation from the congress coordinate these departments that you have in mind?

Dr. Parran:—That authority does exist in the bill. Public health measures for the prevention of disease—my plea is that this bill should not further create confusion and further disperse the present unrelated and scattered federal health activities, and for these reasons: public health measures for the prevention of disease merge naturally with medical service for the advance in treatment of disease. The Public Health Service has had a background of dealing with the states for almost fifty years. We have had no difficulty in administering title VI with the states; there has been no suggestion of federal domination and federal control. There has been, I think, one of the finest examples of federal and state cooperation in administering title VI, and I may say also title V of the Social Security Act.

Accordingly, I urge specifically with respect to Senate 1620 that the adminstrative agency under title XIII be changed from the Social Security Board to the Public Health Service. To promote coordination and joint planning between the several federal agencies—if it is impossible to bring them entirely together—agencies which are administering services under this bill, I recommend that the bill be amended as follows: (1) To provide reciprocal provisions requiring the Public Health Service and the Children's Bureau to establish systems of uniform budgeting, accounting and reporting by state agencies; (2) to provide that rules and regulations regarding payments to states under Sections 504, 514, 604, 1204 and 1304 shall be harmonious and made after joint consultation by the Public Health Service and the Children's Bureau, with a joint conference of the state and territorial health authorities or with the executive officers of other state agencies charged with the administration of services under this act; (3) to provide for a single Federal Advisory Health Council composed of members of the professions and agencies concerned with the promotion of health and medical services and other persons informed on the need for or provision of health and medical services, in place of the several federal advisory councils provided for in sections 506, 516, 606, 1206 and 1306; a great multiplicity of councils exists.

Senator Ellender:—How would you select them, doctor?

Dr. Parran:—If the Children's Bureau and the Public Health Service are the only two agencies dealing with the health and medical aspects of the bill, it would be very simple to have a council of seven, three, let us say, appointed by the—by each of the agencies, and the seventh the chairman of the state and territorial health organization ex officio.

Senator Ellender:—What would be the jurisdiction of that council?

Dr. Parran:—As provided under these several sections. They are advisory councils supposed to advise with respect to the rules and regulations and with the general policies.

Senator Ellender:—Would you have a separate council for each subdivision?

Dr. Parran:—I would have only one for the titles V, VI, XII and XIII.

Senator Ellender:—And another for what?

Dr. Parran:—That is all.

Senator Ellender:—That would be one council; in other words, the council that you suggest would have jurisdiction over the entire works, as it were?

Dr. Parran:—It would replace an unknown number, certainly five councils which are now required under this bill.

Senator Ellender:—How would that be worked in the states, let us say? Would you recommend the same thing, that, instead of having different councils in the states, there be one council in each state?

Dr. Parran:—I hope that the bill would not require additional councils. One or another state would wish to have more, but I hope that the emphasis in the bill would be toward similar joint planning through one council. I am not prepared at the moment to say that I would go so far as to say that there must be only one. Again I think we should leave the states the greatest of freedom.

Senator Ellender:—Your recommendation would be then that one council would be sufficient?

Dr. Parran:—This is a health problem, and that is a unit problem by and large.

Senator Murray:—And a multiplicity of councils would be sure to promote conflicts and different ideas, would it not?

Dr. Parran:—I do not see how it could be avoided.

Senator Ellender:—You would have quite a lot of jealousies among the councils as to whom the money should be allocated, how it should be allocated and all of that? I think your objection is very good and, by the way, one of the witnesses I think testified that 268 or some such number of councils would be organized throughout the country and I believe if we can limit it to one from each state, that is suggested as it were to the states, and have it obligatory so far as the federal government is concerned, that it would be doing very well.

Senator Murray:—Sometimes it is difficult enough to get cooperation with even one council, like the TVA where we found great difficulty.

Senator Ellender:—Doctor, what would be your suggestion as to how the council should be selected in the states?

Dr. Parran:—The state agencies responsible for the administrating or the administering of the several parts of the program should meet on the makeup of the council or, if there is this agreement among them, it should be possible for the governor to straighten out any interdepartmental bickering as to relative jurisdiction.

Senator Ellender:—What if we suggested— it is only a suggestion and we do not want to make the states do it—but as far as we could—there was a witness here who testified that in the state of Kentucky the medical association selected members for certain positions in the boards, and so forth, created under the state law. What would be your view on that?

Dr. Parran:—As I have observed its workings in Kentucky and Alabama, and I think South Carolina, there are three states in which that is the pattern. No other states saw fit to establish the same pattern when their boards were started many years ago.

Senator Ellender:—How has the plan worked in the three states that you have just mentioned?

Dr. Parran:—It seems to have worked well.

Senator Ellender:—Do you know what caused a change in those three states?

Dr. Parran:—There was no change; it was a matter of the original setup back in the days when there were yellow fever epidemics, and these boards of health were organized to meet them. The medical associations were turned specifically to organize the boards in these states and given certain authority under the law. No other state has seen fit, however, to invest responsibility for the health of all the people in one professional group.

Senator Ellender:—You say that so far as the council is concerned here in Washington you would suggest that each division make its own selection or each department?

Dr. Parran:—Joint action.

Senator Ellender:—What if you put them all under one, as we have just been talking about?

Dr. Parran:—As the head of one federal bureau having very harmonious relations with the Children's Bureau, which under the laws going back to 1912 give it certain responsibility for the public health, I think it would be most inappropriate for me to make any suggestions on that score, especially in view of the fact that the Congress has never seen fit to change that setup.

Senator Ellender:—I won't put you on the spot. (Laughter.)

Dr. Parran:—I may say, Mr. Chairman, that in my own experience as Surgeon General we have had nothing but the finest cooperation with the Children's Bureau, and on many occasions we have seen to it that duplication is minimized and that we do work together in the most efficient possible way.

Senator Ellender:—While you are on the subject, how have your relations been with the states?

Dr. Parran:—With the state health departments?

Senator Ellender:—Yes; the various states of the Union.

Dr. Parran:—Dr. McCormick, the state health officer of Kentucky, gave some testimony on that subject speaking for all of the state officers. I subscribe fully to what he said in emphasizing that it has been possible to expend the funds, $8,000,000 a year under title VI, and now another $5,000,000 a year under the venereal disease act and $600,000 under the national cancer act, without any suggestion or complaint from any responsible source concerning unreasonable federal dictation or domination or coercion of the states.

Senator Ellender:—Under the Social Security Act as it is now drafted, most of the plans are really submitted by the states, are they not?

Dr. Parran:—All of them are.

Senator Ellender:—Have you ever actually turned them down and said "We don't want it this way; you must do it that way"?

Dr. Parran:—We have never turned down any whole state plan. As a matter of fact, they are worked out usually in consultation with our representatives, representatives of the Children's Bureau and their own people.

Senator Ellender:—Did you ever attempt to try and have them the same in one state as they have in another, as has been charged?

Dr. Parran:—Quite the contrary. And one of the criticisms so often repeated about this bill is that its provisions are indefinite. That statement has come up time and again in these hearings.

Senator Ellender:—Yesterday on four occasions.

Dr. Parran:—What is the alternative of that? A plan under which the federal government would regiment every township and county health officer and city council into a uniform pattern? I hope not. Another criticism has been made that this bill gives to the federal government unlimited authority and unlimited discretion. If there are ways in which this committee can limit the discretion and the authority in the allotting of money to the states in order to put those allotments on a more objective basis, I should welcome very much such restriction. I should like to point out, however, that the language of this bill restricts my authority much more than the language of the present title VI or the venereal disease control act.

Senator Ellender:—Yesterday or the day before—last week I think it was—one witness said "The first year you are going to spend so much; the second year you are going to spend so much; the third year you are going to spend so much, and the fourth year it is unlimited; think of such a statute as that." They forget that we have to go to the Congress, to some of these hard-boiled senators and congressmen, and have got to show them the necessity for it before they appropriate.

Dr. Parran:—I am sure, Senator, that those people have no concept of the amount of factual data, the extent to which actual need must be demonstrated before the appropriations committees of these two bodies before any monies are appropriated, and especially before any increased monies are given.

Senator Ellender:—If they were to appear before those committees once or twice, they would be convincted of that.

Senator Murray:—Those in favor of balancing the budget laugh away such a thing as that when it is suggested. They think that the opportunities for getting appropriations are unlimited and that all we have to do is to go in and ask for it and that we get it.

Dr. Parran:—In connection with balancing the budget, Mr. Chairman, I hope that this congress will give more attention to balancing our health budget. It is cheaper to keep a woman from dying in childbirth than to take care of the orphans in an orphan asylumn or to give aid to the dependent children. It is cheaper to aid in building tuberculosis sanatoriums than it is to pay for the deaths from tuberculosis and the widows and children who are left. The state health officer of Tennessee made a statement the other day which impressed me very much. He estimates that it costs on the average $150 to bury a person in Tennessee, and on that basis it is costing that state more to bury people dying from tuberculosis than it spends for its entire health program including tuberculosis and all the other diseases.

Senator Murray:—So that money invested in this manner would be wisely invested and would tend to an ultimate balancing of the budget?

Dr. Parran:—It would be a direct economy. I don't know of any more economical expenditure of public funds than those spent wisely for health protection and health promotion.

The provisions of the bill regarding variable grants in aid are believed to be well conceived. They should insure allotments of money only to meet demonstrated health needs. If the poorer states are to have adequate health programs, it is essential that the federal government contribute a larger share of each dollar expended in these states than in the states having greater

economic resources. Under title VI of the present Social Security Act, the Public Health Service has been enabled to allocate funds in part from the financial and special health needs of the states. For example, the per capita allotments budgeted by the states from federal funds under this title for the present fiscal year vary from 5 cents to 41 cents.

Finally, may I say, Mr. Chairman, that this is not a measure to socialize medicine in the country. Quite the contrary; it is a measure which will free medicine to render better service to all the people. It proposes to share, to socialize more of the costs of medicine, but not to socialize medicine. The objectives of the bill can be attained without any basic change in the practice of medicine in this country.

Senator Ellender:—Doctor, how would the passage of this bill, let us say, and making it effective, affect the pocketbooks of the doctors?

Dr. Parran:—Obviously the $50,000,000 proposed to be allotted the first year under title XIII for the care of needy patients would go in large part to the physicians as well as to existing hospitals. Some of this great load of charity which the doctors carry and under which many of them are staggering would be lessened.

Senator Murray:—Doctor, during the serious conditions under the depression, is it not a fact that in many sections of the country many of the doctors were kept in practice by the moneys that they received through grants from the relief organizations?

Dr. Parran:—It is quite true, and it is still true, Mr. Chairman, that in many rural sections the only thing that enables the doctor to buy his gasoline or pay his office rent is the little money that he gets from current relief funds for the care of indigent patients.

Dr. Parran then discussed dental hygiene and the effects of the Wagner Health Act on the drugless healer. He also described the work of the United States Public Health Service and the manner in which the United States Public Health Service has cooperated with various state and county medical societies, with the American Medical Association and the medical schools. Special attention was also given to the problems of silicosis and malaria.

Senator Murray:—Well, doctor, we appreciate your testimony and hope that we may continue in contact with you during the further study of the problem. I am satisfied from your statement that we are going along the right lines, and all we need to do is to make the necessary amendments and corrections to the bill to carry out the purposes that we have in mind that you have so well expressed this morning.

Dr. Parran:—Thank you very much, Senator.

May I say just another word and thank you for the opportunity to be here? I was told this morning that the chairman of the subcommittee made a statement yesterday to the effect that he did not expect any final action of Congress on this whole bill at this session of the Congress. May I urge that at least the next step or two will be taken in regard to these matters, which are not controversial, and in regard to which there is great and obvious need? By so doing, we can begin to build up toward the whole program of public health if it is not possible to proceed on all fronts at this time.

Senator Ellender:—The great difficulty in separating it is that you separate the easy ones from the hard ones and leave the hard ones out, and if you do that you may never get the hard ones through.

Dr. Parran:—I had not thought of that.

Senator Murray:—They are talking about adjourning by the 15th of July, doctor, and there are so many other bills ahead of this that it seems to me impossible to get this bill reported, because it will take time, considerable time, to transcribe this testimony and have it printed and then act on all of the amendments that are going to be considered; and then we want to give full consideration and study to every proposal that has been made, every criticism that has been made against the bill, and it would seem to me that it would be utterly impossible to give the proper consideration to the bill and get it up on the floor at this session.

Dr. Parran:—I can realize those very great difficulties.

Senator Murray:—I would like to see it done, if it is possible. If we had started earlier it might have been possible, but when we are in the present situation that we are now, and the testimony not yet concluded, I do not see how it is going to be possible.

Dr. Parran:—Thank you very much.

STATEMENT BY ARTHUR J. ALTMEYER

Mr. Arthur J. Altmeyer, chairman of the Social Security Board, described the work of the Social Security Board and the Interdepartmental Committee to Coordinate Health and Welfare Activities, stating that the Social Security Board has already endorsed the principal objectives proposed in S. 1620. He considered particularly the new functions given to the Social Security Board under titles 13 and 14 in the Wagner Health Act. Mr. Altmeyer again cited the 40,000,000 persons in the United States with incomes of less than $800 a year and stated that there were 21,000,000 persons with families dependent in whole or in part on local, state and federal governments for food and shelter and likewise dependent on private aid or philanthropy for medical care in sickness. An additional 20,000,000 he included in a marginal group which can purchase medical care only at the risk of curtailing food, clothing and shelter. He also stated that this is left only to local responsibility now and that medical care for this marginal group was inadequate. Mr. Altmeyer again made the statement so frequently used by Miss Josephine Roche that no one at the National Health Conference took exception to or raised a question concerning the picture of unmet needs. He felt that under title 13 states can develop plans to level the economic barrier by distributing costs among large groups of persons and over periods of time, saying "whether the states choose to do this through tax supported service, through social insurance or through a combination of the two, is a matter for them to decide." He also said that he did not think this would interfere in any manner with the medical profession as it operates now and that such changes would benefit the medical profession financially. Quoting:

Mr. Altmeyer:—Yes, financially, and I think professionally. I see no reason why the introduction of a systematic provision for spreading the cost of medical care not only should protect the services that we have now, the quality of the services that we have now, but would advance it. It all depends on how the thing is worked out. That is the job of an administration always, to bring in the technical groups and to bring in the groups who are interested in the effect. Not only the consumers, but the producers. That is the only way that we can get proper administration, but all parties in interest have a right to express themselves and to help in the development of the administrative machinery and its working.

Senator Murray:—Many of us would hesitate to do anything or approve of any bill that would in any manner break down the medical profession, and I think that the testimony that you are giving is important from the standpoint of wanting to protect the medical profession in every way from having their profession broken down. If this could be done without necessarily interfering with the medical profession, but on the contrary benefiting it, I do not see any reason why it should not be done.

He then further analyzed the various sections of titles 13 and 14 of the proposed act.

Afternoon Session

STATEMENT OF DR. LESLIE R. BURDETTE

Dr. Leslie R. Burdette, president of the American Optometric Association, presented a statement on deficiencies of eyesight, pointing out that an urgent need exists that is not due to a lack of qualified ophthalmologists and optometrists but to a low economic status of a great portion of our population. He recommended that projects be approved for the purposes of providing an annual examination for all school children and that the service of optometrists can be utilized in industrial hygiene activities. Under title 13 of the act he recommended that a periodic eye examination should be part and parcel of the program to be inaugurated. He said that telescopic spectacles, pinhole spectacles, microscopic spectacles and cataract lenses have proved their value in rehabilitation of the adult and that children have been rehabilitated by the use of telescopic spectacles. He told how optometrists cooperate with ophthalmologists, saying "we cooperated with ophthalmologists by securing and referring to them for treatment the cases of pathology." He said that under the proposed bill the optometrists of the country should rightly be allotted that portion of the work which is particularly within their field.

STATEMENT BY MR. M. LUTHER DICUS

Mr. M. Luther Dicus, third vice president and chairman of the Committee on National Affairs of the American Optometric Association, said "The specific purposes of the suggestions with which I shall close this statement is to guarantee that the people of this country on the enactment of S. 1620 shall have a continuation of the professional services rendered by optometrists and that optometry shall not be excluded from the operation of the act, directly or by implication."

He reviewed the history of social security legislation and of optometry and suggested some amendments which would include optometry in various sections of the act.

He also filed a statement by William B. Needles, president of the Northern Illinois College of Optometry, discussing educational standards of optometry.

STATEMENT OF MR. HAROLD KOHN

Mr. Harold Kohn, national counsel, American Optometric Association, stated that the legislative body of the American Optometric Association will meet on June 25 and will make further suggestions relative to the act.

Senator Murray:—That would be very satisfactory. You may do that. As far as I understand it, there is no conflict between ophthalmology and optometry? Ophthalmology deals with the organic diseases, those which the ophthalmologist may find in the eye, and the optometrist does the mechanical work?

Mr. Kohn:—Determining the refractive error.

Senator Murray:—And some of the finest people in the country patronize the optometrist without ever going to the ophthalmologist at all, is that not so?

Mr. Kohn:—That is; 72 per cent of them, by actual statistics. If the examination discloses a condition requiring the attention of an ophthalmologist, they are immediately sent to them.

Senator Murray:—So that there is no lack of harmony between the two professions?

Mr. Kohn:—Generally speaking, absolutely not. Once in a while there is a little professional jealousy in small communities. That sometimes happens but that is very rapidly being overcome through interprofessional relationship committees of the Ophthalmological Association and of our association.

STATEMENT OF MISS KATHARINE LENROOT

Miss Katharine Lenroot, chief, Children's Bureau, Department of Labor, described the development of the Children's Bureau and stated that the amendments proposed in S. 1620 would build on the foundation previously laid.

With the exception of increased amounts authorized, and a broadening of the maternity care program and extension of medical care to other classes of children than those now covered, the only changes in the proposed bill relate to methods of allotting and paying funds, matching provisions, conditions of approval of state plans, provision for a federal advisory council or councils, and authority to make rules and regulations. Though the provision for medical care of children is included in part 2 of title V for certain administrative reasons, it would appear that similarity of the conditions of allotment, payment and approval of plans under parts 1 and 2 would make it possible for a state to submit a single plan for maternal and child health, including maternity care and medical care of children, provided that under state law the state health agency has jurisdiction in these fields or can develop working agreements with other state agencies now charged with such responsibilities under state law.

There are now twenty-six states that administer the crippled children's program through the health departments, and the others administer that program through other departments of the state government at the present time. In many states responsibility for medical care of children is in some state agency other than the state health agency.

It would appear to be of utmost importance that medical, nursing and hospital care, provided for women at childbirth and for children when sick, be under the same state and local agencies as those providing preventive services. Under part 1 of title V as amended in the pending bill the state health agency is given full administrative authority, as under the present provisions of title V, part 1 of the Social Security Act. Under part 2, though, for a period of five years other state agencies may administer medical services for children or services for crippled and other physically handicapped children, at the end of that time responsibility would be given to the state health agency and a single plan of service could be developed for all maternity and child health work within the state. Such a plan to coordinate these services under the state health agency seems to be highly desirable and entirely feasible from an administrative point of view.

She then presented a statement by Dr. Eliot showing the present provisions of title V, parts 1, 2 and 5, and the proposed amendments; also a statement from the Secretary of Labor, indicating the desire of the Labor Department to retain the Children's Bureau.

STATEMENT OF DR. MARTHA M. ELIOT

Dr. Martha M. Eliot, assistant chief, Children's Bureau, favors the bill as a means of expanding the work of the Children's Bureau. She gave a record of the work thus far accomplished.

STATEMENT OF MR. V. A. ZIMMER

Mr. V. A. Zimmer, representing the United States Department of Labor, stated that he is director of the Division of Labor Standards of the United States Department of Labor. He said that the Secretary of Labor and the department feel that it is very important that allotments for industrial hygiene activities belong in the state agency charged with the responsibility of regulating conditions of employment in industry. They objected specifically to the placing of such work under the state health agency. He stated that industry and hygiene is not a medical question but essentially an engineering proposition.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. 1021 has been reported to the Senate, proposing to extend the benefits of the United States Employees' Compensation Act to members of the Officers' Reserve Corps and of the Enlisted Reserve Corps of the Army who are physically injured while performing active duty or engaged in authorized training. S. 2353 has passed the Senate, proposing to authorize an appropriation not to exceed $375,000 for the construction, rehabilitation and installation at Carlisle Barracks, Pennsylvania, of a medical field service school and such utilities and appurtenances thereto as may be necessary.

Bills Introduced.—S. 2575, introduced by Senator Hill, Alabama, proposes that all reserve officers of the army of the United States who were called or ordered into active military service by the federal government for extended military service in excess of thirty days on or subsequent to July 1, 1928, and who suffered disability or death in line of duty shall be entitled to receive the same pensions, compensation, retirement pay and hospital benefits as are now or may hereafter be provided by law or regulation for officers of corresponding grades and length of service of the Regular Army. H. R. 6576, introduced by Representative Gross, Pennsylvania, proposes to authorize the Secretary of Agriculture, in the interests of the public health and as a relief to the dairy industry of the country, to prepare and cause to be published a series of articles and advertisements promoting the consumption of milk and derivative dairy products. H. R. 6723, introduced by Representative Mundt, South Dakota, proposes to enact a "Navigable Waters Anti-Pollution Act" to be administered under the direction of the Chief of Engineers of the United States Army under the supervision of the Secretary of War.

DISTRICT OF COLUMBIA

Change in Status.—S. 1805 has passed the Senate, proposing to establish a lien for moneys due hospitals for services rendered in cases caused by negligence or fault of others. The bill contains no provision for a lien in favor of a physician who renders services under similar circumstances.

SICKNESS UNDER INSURANCE

It is generally agreed that the average worker in the United States loses about nine days annually from sickness. W. D. Jenkins, chief medical officer of the South Metropolitan Gas Company, London, in a recent address said,[1] concerning insured British workers:

> In this country there are about 15,000,000 insured workers who, it is stated, in an average year lose 30,000,000 working weeks through sickness annually. This is equivalent to the year's work of some 600,000 people, or an average annual absenteeism of ten days for men and twelve for women. It is true that these figures cover all grades of insured workers and do not represent illness arising solely among those engaged in industry. On the other hand, they do not cover absences of three days or less.

1. J. Roy. Inst. Pub. Health & Hyg. 2: 178 (March) 1939.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Outbreak of Gonococcic Ophthalmia.—A gonococcic infection was said to be the cause of a recent outbreak of thirty-nine cases of ophthalmia in a rural school having an enrolment of 140. Some of the patients were convalescent when first seen, but nine of the cases were proved to be due to the gonococcus. The disease was introduced into the school by a boy who had acquired the infection from an adult similarly infected. When all the pupils were examined for genital infection, none of the boys was found infected but seven small girls were found to have gonorrheal vaginitis.

ARKANSAS

Appropriation to Medical School Increased.—The Arkansas legislature recently granted to the University of Arkansas School of Medicine, Little Rock, an increase in its annual appropriation from $70,000 to $300,000. The increase was granted chiefly to enable the school to take over the Little Rock City Hospital, with a capacity of 200 beds, adjoining the medical school.

CALIFORNIA

Hospital News.—A contract has been let for a new wing, costing $225,000, at the Palo Alto Hospital; construction is to begin immediately.

Plague Infection.—Plague infection was proved in three ground squirrels, Citellus beecheyi, submitted to the laboratory of the state department of health April 18, from a ranch on Casitas Pass Road, Ventura County, 2 miles east of the Santa Barbara County line, according to *Public Health Reports*.

Society News.—Dr. Albert H. Rowe, Oakland, addressed the Butte County Medical Society in Chico on "Allergy and Its Manifestations" recently.——Dr. George Joyce Hall, Sacramento, discussed "Clinical Evaluation of Endocrine Therapy in Menstrual Disorders" before the Hollywood Academy of Medicine June 8.——The section on medicine and pediatrics of the San Francisco County Medical Society held a special meeting June 6 with Drs. Garnett Cheney and Jesse L. Carr speaking on "Clinical Application of Vitamin K" and "Laboratory Methods of Vitamin Determination (A, B, C, Nicotinic Acid, and Their Clinical Application" respectively.

CONNECTICUT

Personal.—Dr. Ross G. Harrison, Sterling professor of biology, emeritus, Yale University, New Haven, delivered the Linacre Lecture at St. John's College, Cambridge, England, May 16, on development of the internal ear, a study in experimental embryology.——A testimonial dinner was recently held in Bridgeport in honor of Drs. James D. Gold, chairman of the council of the state medical society, and Daniel C. Patterson, a recent president of the state board of medical examiners. ——Dr. Perry T. Hough has been appointed medical examiner in Hartford, succeeding Dr. Henry N. Costello.

Grant Supports Work in Biology.—Yale University has received from the Rockefeller Foundation a grant-in-aid of $189,000 toward the continued support of the Yale Laboratories of Primate Biology for the five year period July 1, 1939, to June 30, 1944, and also $35,000 for the construction of an additional laboratory building at the Anthropoid Station at Orange Park, Fla. According to *Science*, under the reorganization of the laboratories, following the ten year period for which the project was originally financed, the director, Robert M. Yerkes, Sc.D., will be responsible to an administrative committee, serving as a board of control. Members of this committee include Carl G. Hartman, Ph.D., research associate in embryology, Carnegie Institution, Johns Hopkins University School of Medicine, chairman; Edgar Allen, Sc.D., professor of anatomy at Yale; Leonard Carmichael, Ph.D., president of Tufts College, Boston; William H. Taliaferro, Ph.D., dean of the Division of Biological Sciences, University of Chicago; Dr. Yerkes, professor of psychobiology at Yale, secretary, and Dr. Stanhope Bayne-Jones, dean of the Yale school of medicine, member ex officio.

GEORGIA

Personal.—Dr. Charles L. Ridley, superintendent of the Macon Hospital, Macon, has been appointed a member of the state board of health, succeeding Dr. Allen R. Rozar, whose six year term expired some months ago, according to the *Modern Hospital*. Dr. William P. Harbin, Rome, has also been appointed a member.

Annual Clinic Week.—Emory University held its annual clinic week at Grady Hospital, Atlanta, May 30-June 2. The program included lectures, clinics and symposiums. One session was a joint meeting with the Fulton County Medical Society. At the annual banquet at the Henry Grady Hotel, Dr. Frank K. Boland Sr. was the guest speaker.

ILLINOIS

Hospital News.—The Commonwealth Fund has offered to contribute not less than $225,000 to build and equip a community hospital in Pittsfield, provided that the people of the area to be served raise an additional $60,000 by July 1, according to *Hospitals*.

Mosquito Abatement Campaign.—A survey to determine the cheapest way to destroy mosquitoes was decided on May 19 by the Tri-County Mosquito Abatement Committee, made up of representatives from Lake, DuPage and Cook counties, newspapers reported recently. When the plans have been completed they will be made the basis of a proposal for a WPA project, it was stated.

Chicago

Wanted—Patients with Essential Thrombocytopenic Purpura.—Members of the department of medicine of the University of Illinois College of Medicine are interested in the study of essential thrombocytopenic purpura. Patients with this disease will be accepted in the Research and Educational Hospitals without charge provided they are referred by their family physician. Letters should be addressed to the head of the department of medicine of the university.

Society News.—At a meeting of the Chicago Society of Allergy June 10, Drs. Isidor Harrison Tumpeer spoke on "A Dramatic Asthmatic" and Rudolph Hecht on "Sensitization to Simple Chemicals: Reactions to Commercial and Purified Lipstick Dye."——Dr. Leon Unger addressed the Chicago chapter of the American Physiotherapy Association June 7 on "Allergy in General."——Dr. Disraeli W. Kobak discussed "Advances in Short Wave Therapy" before the McDonagh Society for Clinical Research May 31.

INDIANA

Veteran Teacher Honored.—Dr. Alois B. Graham, professor of surgery (proctology), Indiana University School of Medicine, Indianapolis, was honored at a meeting in the James Whitcomb Riley Memorial Hospital May 8, marking his retirement from the medical school faculty after forty years' service. Dr. Graham was presented with a portable radio and a gold medal. He was president of the Marion County Medical Society in 1916, of the Indiana State Medical Association in 1929, of the American Proctologic Society in 1919, and chairman of the Section on Gastro-Enterology and Proctology of the American Medical Association in 1928. During the World War he served as chief surgeon of base hospital number 32 in France.

IOWA

Personal.—Dr. William O. Smouse, Des Moines, was elected a life member of the Iowa State Medical Society at its recent annual session.——Dr. John C. Dennison, Bellevue, recently completed fifty years in the practice of medicine.

Society News.—At a meeting of the Des Moines Academy of Medicine and the Polk County Medical Society May 23 Drs. Floyd A. Springer discussed "Treatment of Carcinoma of the Breast" and John W. G. Caldwell, "Diagnosis and Treatment of Coma."——Dr. Verl A. Ruth, Des Moines, addressed the Henry County Medical Society in Mount Pleasant recently on back injuries.——The Woodbury County Medical Society was addressed recently in Sioux City by Dr. Archibald F. O'Donoghue on "Injuries to the Spine and Pelvis."

Spotted Fever.—From May 20 to 27 six cases of Rocky Mountain spotted fever with two deaths were reported to the state department of health, according to the state medical journal. The youngest patient was a farm boy, aged 5, in Davis County, while the oldest was a farmer and trucker,

aged 57, in Van Buren County. Other cases were: Farm girl, aged 12, in Clarke County; carpenter, aged 52, Woodbury County; carpenter, aged 49, Boone County, and housewife, aged 25, Tama County. One of the deaths occurred in an Indian woman at the Sac and Fox Reservation in Tama County, from which locality six cases (with two deaths) were reported in the summer of 1937. According to the state medical journal, it is as yet uncertain whether the second fatality was caused by Rocky Mountain spotted fever or by overwhelming infection associated with a fulminating type of purpura.

KANSAS

Society News.—The Sedgwick County Medical Society was addressed recently by Drs. Frederick W. Matassarin on "Rose Operation: for Repair of Trigonal Muscle (Incontinence in the Female)" and James S. Hibbard Jr., "Surgical Treatment of Hypertension."

LOUISIANA

Committee on Industrial Health.—The Louisiana State Medical Society has organized a committee on industrial health composed of the following: Drs. Shirley C. Lyons, New Orleans, chairman; Edward P. A. Ficklen and William H. Perkins, both of New Orleans; William V. Garnier, Bastrop, and Isaac L. George, Baton Rouge.

Society News.—At a special scientific meeting of the Orleans Parish Medical Society with the Tuberculosis and Public Health Association of Louisiana May 22, Drs. Julius L. Wilson discussed "Tuberculin Testing in Public Schools"; Leon J. Menville, "X-Ray in the Early Diagnosis of Pulmonary Tuberculosis," and Edgar Hull, "Clinical Value of the Early Diagnosis of Pulmonary Tuberculosis." The society was addressed May 8 by Drs. Manuel Gardberg on "Treatment of Diabetes Mellitus"; Joseph O. Weilbaecher Jr., "Acute Spinal Epidural Abscess with Report of Four Cases," and Frederick F. Boyce, "Mortality of Thyroid Disease in a Nonendemic Area: An Analysis of 102 Consecutive Deaths, with a Special Note on the Liver Factor."

MASSACHUSETTS

Personal.—Leroy M. S. Miner, M.D., D.D.S., dean, Harvard Dental School, Boston, and former president of the American Dental Association, was recently awarded the Jarvie Fellowship Medal by the Dental Society of the State of New York; this medal is presented each year in recognition of outstanding contributions to the dental profession, according to the *New England Journal of Medicine.*

MICHIGAN

Hospital News.—A new $350,000 hospital at Petoskey, to be called the Little Traverse Hospital, was recently opened; Dr. Dean C. Burns is director.

Institutes on Tuberculosis.—The state department of health is sponsoring a series of institutes on tuberculosis control for public health personnel throughout the state, according to the state medical journal. The institutes opened May 15 and feature the medical aspects of tuberculosis control and the part played by the public health nurses. The diagnosis and treatment of the disease from the point of view of the sanatorium specialist is also being considered.

Changes in Health Officers.—Dr. Willard G. Beattie, Ferndale, has resigned as city health officer, effective May 15, to devote his time to private practice, it is reported.—Dr. Edwin H. Place, Midland, who has been attending the University of Michigan School of Public Health on a leave of absence, has resigned as health officer of Midland County. According to the newspapers, Dr. Place has accepted a fellowship for study in public health with the Kellogg Foundation of Battle Creek.

New County Medical Society.—The Van Buren County Medical Society, formerly affiliated with the Kalamazoo Academy of Medicine, has been organized as a separate entity with the following officers: Drs. William P. Bope, Decatur, president; Ronald W. Spalding, Gobles, president-elect; Charles Ten Houten, Paw Paw, secretary, and Arthur H. Steele, Paw Paw, treasurer. The speakers at the new society's initial meeting included Drs. Paul R. Urmston and L. Fernald Foster, Bay City, and William A. Hyland, Grand Rapids. A charter was granted to the woman's auxiliary at the same time.

MINNESOTA

Society News.—At a meeting of the Scott-Carver County Medical Society recently Dr. Edgar W. Bedford, Minneapolis, discussed "The Clinical Aspects of Gallbladder Disease" and Dr. Ames W. Naslund, St. Paul, "X-Ray Diagnosis in Gallbladder Pathology."—Dr. William de B. MacNider, Chapel Hill, N. C., gave a Mayo Foundation Lecture at the Mayo Clinic, Rochester, recently entitled "Concerning Tissue Resistance and Tissue Adaptations."

Special Lectures at University.—Dr. August Krogh and his wife, Dr. Marie Krogh, of the University of Copenhagen, were guests of the University of Minnesota Medical School, Minneapolis, for ten days recently. During their visit Dr. Krogh presented lectures and seminars on the following subjects: "Osmotic and Ionic Regulation in Animals," "Circulatory Adjustment to Posture in Man," and "Comparative Physiology of Respiration." Dr. Marie Krogh lectured on "Nutritional Problems in Denmark."

MONTANA

Railway Surgeons' Meeting.—The Great Northern Railway Surgeons' Association will hold its annual meeting at Glacier Park Hotel, Glacier Park, June 30-July 1. The tentative program includes the following speakers:

Dr. Cyril J. Glaspel, Grafton, N. D., Management of Traumatic Wounds.
Dr. Hiram E. Cleveland, Burlington, Wash., Repair of Tendons.
Dr. Howard J. Knott, Seattle, Wash., Rupture and Repair of an Ossified Tendon of Achilles.
Dr. James E. Reeder, Sioux City, Iowa, *Emergency Ophthalmology.*
Dr. Frederick A. Kiehle, Portland, Ore., Management of Opacities of the Cornea.
Dr. Charles B. Wright, Minneapolis, Coronary Disease Among Railroad Employees.
Dr. Herbert E. Wheeler, Spokane, Wash., Tetanus: Report of a Case Complicated by Lordosis.
Dr. Axcel C. Baker, Fergus Falls., Minn., Osteomyelitis.
Dr. George N. Pease, Portland, Traumatic Appendicitis.
Dr. Arthur N. Collins, Duluth, Minn., Traumatic Rupture of the Kidney.
Dr. Roscoe C. Webb, Minneapolis, Traumatic Rupture of the Normal Spleen with Delayed Hemorrhage.
Dr. Otto W. Scholpp, Hutchinson, Minn., Disability of the Knee Joint Following Injury.
Dr. Otto W. Yoerg, Minneapolis, Fractures of the Os Calcis.
Dr. Berton J. Branton, Willmar, Minn., Fractures of the Metatarsal Bones.

NEW YORK

Annual Conference of Health Workers.—The Annual Conference of Health Officers and Public Health Nurses will be held at Saratoga Springs June 27-29 and the New York State Association of School Physicians will meet June 26. Governor Lehman, Surgeon General Thomas Parran of the U. S. Public Health Service, Washington, D. C., and Abel Wolman, Dr. Eng., Baltimore, president of the American Public Health Association, will be among the speakers. At one session three men who have been members of the state Public Health Council for twenty-five years will review the council's work: Dr. Simon Flexner and Mr. Homer Folks, New York, and Prof. Henry N. Ogden, Ithaca. Other speakers will include:

Dr. Karl F. Meyer, San Francisco, Equine Encephalomyelitis.
Dr. John E. Gordon, Boston, Epidemic Problems in Virus Disease.
Earle W. McHenry, Ph.D., Toronto, Results of a Dietary Survey in Toronto.
Dr. Maxwell Finland, Boston, The Use of Sulfapyridine in Pneumonia.

Among those who will address the school physicians are:

Dr. Herbert W. Schmitz, Yonkers, The School and the Cardiac Child.
Helen M. Manzer, Ph.D., New York, Recent Trends in Health Education.
Dr. Charles H. Keene, Buffalo, The Physician Considers "Physical Fitness Tests."
Dr. Rudolph Ruedemann Jr., Albany, Combating Skin Infections of School Children.

New York City

Unlicensed Practitioner Convicted.—Frederick C. Zinke, a chiropractor, was convicted May 24 in the court of special sessions of practicing medicine without a license. He received a sentence of three months in the workhouse, with execution suspended.

Course on Eye Conditions for Lay Workers.—New York University announces that a course entitled "Survey of Eye Conditions" will be given during the summer session in cooperation with the bureau of service for the blind, New York State Department of Social Welfare. It is designed for workers

in education, social welfare, public health nursing and allied fields to present a background of the conservation of vision. Inquiries may be addressed to Mr. James Meyers, director of the course, School of Education, New York University, Washington Square.

County Library Report.—The library of the Medical Society of the County of Kings and the Academy of Medicine of Brooklyn recently reported that greater use was made of the library in 1938 than in the previous year. The number of readers increased from 16,570 to 17,055. The library received support from the general funds of the society, from numerous local societies that hold meetings in the county society's building and from other organizations. The library purchased 245 books and 855 volumes of periodical publications or back files. It received regularly 1,545 current serial publications.

The WPA Reports.—Included in the WPA projects in New York in 1938 were many concerned with health and medical services. Of a total expenditure of $157,659,628 of WPA funds for all purposes, $7,648,629 was used for projects sponsored by the department of health and $6,666,348 for projects sponsored by the department of hospitals. To the total WPA funds the city added $28,408,354 for materials, the state $409,306 and various federal departments $460,878. Among new buildings constructed was one hospital; seventy-seven hospitals were enlarged and improved. Included in health projects was the tuberculosis service, under which 162,984 visits were made to homes and 63,753 persons had x-ray examinations. More than 20,000 children from 1 to 6 years old are under care at the five centers of the Children's Health Service. The housekeeping service for chronically ill persons in their homes has a total of 3,200 cases under its care. Three thousand children monthly receive lip reading instruction. Workers have made 53,000 visits to follow-up patients with syphilis and gonorrhea who fail to return to health department clinics for treatment. Other workers are rendering aid to the sick in twenty-six municipal hospitals. The New York Tuberculosis and Health Association has sponsored a study making an analysis of the course of rheumatic heart disease from complete records of persons who have died. At Memorial Hospital studies in atomic physics and the biologic effects of radiation are being aided.

NORTH CAROLINA

Poliomyelitis Is Not Epidemic in North Carolina.—Dr. Carl V. Reynolds, state health officer, issued a statement June 12 denying rumors that poliomyelitis is epidemic in North Carolina. Actually the incidence of the disease in the state has been below normal for the year, Dr. Reynolds said. There have been eight cases in the period January to June 10 and five of those occurred between January and April. One was reported May 1 and another May 11. None of these is in an infectious stage. Only one case could be considered infectious, one that developed in Greene County June 1. North Carolina had an epidemic with 675 cases in 1935 and it is believed that that epidemic affords protection for the present. Dr. Reynolds advised that persons should not come out of infected regions into uninfected areas, but there is no reason for travelers to avoid North Carolina, he declared.

NORTH DAKOTA

Personal.—Dr. Alfred R. Sorenson, Minot, has been appointed city health officer succeeding Dr. John L. Devine, according to the *Journal-Lancet*.——Dr. Harvey J. Skarshaug, Fargo, has resigned as city health officer to engage in private practice in Colorado.

OHIO

Plan Museum of Health and Hygiene.—Plans for a museum of health and hygiene have recently been launched in Cleveland. A building at 8811 Euclid Avenue has been donated for the museum by Mrs. Francis F. Prentiss and a campaign for supporting memberships has been started. Dr. Jacob E. Tuckerman is chairman of a committee of the Cleveland Academy of Medicine for the campaign.

Alumni Reunion.—The annual reunion at the University of Cincinnati College of Medicine was held June 10. The morning was devoted to grand rounds at the Cincinnati General Hospital with Dr. Mont R. Reid on the surgical service, Dr. Albert Graeme Mitchell on the pediatric service and Dr. Marion A. Blankenhorn on the medical service. A banquet was held at the Netherland-Plaza Hotel in the evening with Dr. Carl A. Wilzbach, health commissioner of Cincinnati, as the speaker.

OKLAHOMA

New Health Officers.—Dr. Daniel E. Little, Eufaula, has been appointed health superintendent of McIntosh County and Dr. John W. Francis, Perry, of Noble County.——Dr. Waldo B. Newell Jr., Enid, has been appointed superintendent of health of Garfield County, effective April 1, succeeding the late Dr. William W. Gill, Enid.——Dr. Joseph Fulcher was placed in charge of the new clinic for the treatment of venereal diseases opened April 20 by the Tulsa department of health.

Society News.—Dr. George S. Baxter, Shawnee, discussed "Acute Appendicitis in Children" before the Pottawatomie County Medical Society, Shawnee, May 13.——The Garfield County Medical Society met with the Kay County society in Ponca City May 25 for a program on office gynecology presented by the following Garfield County physicians: Drs. J. Wendell Mercer, Julian Feild, Marion E. Sheets, Glenn Francisco, George O. Miles, Francis M. Duffy, Bruce R. Hinson and Frederick A. Hudson. All are from Enid.

PENNSYLVANIA

Society News.—Dr. Julia Faith S. Fetterman, Philadelphia, addressed the Delaware County Medical Society, Chester, May 11 on "The Effects of Cancer of the Uterus and Its Treatment on the Urinary Tract."——Dr. James Alexander Miller, New York, addressed the Northampton County Medical Society May 19 on "The Modern Approach to Diagnosis."——Dr. Joseph H. Barach, Pittsburgh, addressed the Mercer County Medical Society, West Middlesex, May 10 on "Newer Aspects in the Treatment of Diabetes." Dr. Barach addressed the Blair County Medical Society, Altoona, May 23 on "Newer Insulins and the Modern Treatment of Diabetes."

Philadelphia

Birthday Dinner for Dr. Coates.—A dinner in honor of Dr. George M. Coates, professor of otolaryngology, University of Pennsylvania School of Medicine, was held at the Warwick Hotel May 27 to celebrate his sixty-fifth birthday. Dr. James A. Babbitt was toastmaster and the speakers included Drs. Benjamin H. Shuster; Chevalier Jackson; Isadore Friesner, New York; Ralph A. Fenton, Portland, Ore.; Burt R. Shurly, Detroit; Joseph C. Beck, Chicago, and Harris P. Mosher, Boston.

Pittsburgh

Alumni Meeting.—The annual homecoming of the Medical Alumni Association of the University of Pittsburgh was held June 10. A portrait of the late Dean Raleigh R. Huggins was presented to the university by Dr. James D. Heard on behalf of the alumni and accepted by Dr. William S. McEllroy, the present dean of the medical school. Dr. McEllroy and Dr. Thomas B. McCollough were the speakers at a luncheon at the Pittsburgh Athletic Club.

RHODE ISLAND

Society News.—Drs. Jacob E. Greenstein, Providence, and Raymond E. Stevens, Rumford, addressed the Pawtucket Medical Association April 20 on "Treatment of a Series of Twenty-Five Cases of Pneumonia at the Memorial Hospital with Sulfapyridine."——At a recent meeting of the Rhode Island Society for Neurology and Psychiatry in Providence Drs. Hiram Houston Merritt, Boston, and Frances Cottington, now of Memphis, Mich., spoke on "The Diagnosis and Treatment of Epilepsy" and "The Present Status of Metrazol in the Treatment of Mental Disease" respectively.

SOUTH CAROLINA

Personal.—A silver service was presented to Dr. Leonidas M. Stokes, Walterboro, by the alumni association of the Medical College of the State of South Carolina during a meeting of the First District Medical Society in Walterboro in May. The presentation was made by Dr. James R. Des Portes, Fort Mill, immediate past president of the South Carolina Medical Association and president of the alumni association. Dr. Des Portes reviewed Dr. Stokes' contributions to the advancement of the college and the medical profession and other speakers were Drs. Douglas Jennings, Bennettsville, president of the state association, Charles R. May, Bennettsville, a former president, and Dr. Edgar A. Hines, Seneca, secretary-editor.

TENNESSEE

Regional Meetings.—The Middle Tennessee Medical Association met in Columbia May 25-26. Among the speakers were Drs. William R. Cate, Nashville, on "Auricular Fibrillation: Its Significance and Management"; Barney Brooks, Nashville, "Surgery of the Gallbladder"; Thayer S. Wilson, Gordonville, "Sulfanilamide and Sulfapyridine and Report of Its Use in Smith County"; Hollis E. Johnson, Nashville, "Diagnosis of Pulmonary Tuberculosis," and Eustace C. Mason, Quebeck, "Serum Treatment of Pneumonia."——The West Tennessee Medical and Surgical Association met in Huntington May 25.——The Tennessee Valley Postgraduate Medical Assembly will hold its fifth annual meeting in Knoxville June 28-30.

TEXAS

Society News.—Dr. Howard K. Gray, Rochester, Minn., was guest speaker before the Texas Surgical Society in Fort Worth at its semiannual meeting recently on "Problems Encountered in Surgery of the Biliary Tract."——Dr. Lester W. Baird, Temple, among others, addressed the Bell County Medical Society in Temple recently on regional enteritis.——Dr. Alfred L. Ridings, Sherman, addressed the Grayson County Medical Society recently on "Danger Points of Thyroid Surgery."——Drs. Felix P. Miller and Francis C. Goodwin, El Paso, addressed the Tom Green Eight Counties Medical Society, San Angelo, in April on "Chest Surgery in Tuberculosis" and "Lateral Bone Traction in the Treatment of Scoliosis" respectively.

WASHINGTON

Hospital News.—A full length oil portrait of the late Dr. James Tate Mason, Seattle, who died shortly after he was made President of the American Medical Association in 1936, was presented to the Virginia Mason Hospital by the alumnae of the nursing school. The presentation was made at a banquet at the hospital May 27.

Society News.—Dr. Jay Arthur Myers, Minneapolis, was the guest speaker at the annual meeting of the Washington Tuberculosis Association June 1-3 in Spokane.——A symposium on tuberculosis was presented at the annual meeting of the Kings County Medical Society, Seattle, June 5 by Drs. Byron F. Francis and John F. LeCocq, Seattle, and John W. Skinner, Kirkland. Dr. Alexander H. Peacock has recently presented to the society a portrait of the late Dr. James B. Eagleson, who was active in the establishment of the society's library and of *Northwest Medicine*.

Outbreak of Typhoid.—Eighty-two school children and one teacher in the town and area surrounding Sequim have typhoid, the Associated Press reported June 10. State and county health officials and the Red Cross began mass immunization. Investigation of possible sources of the disease revealed that 200 buns left over from a traveling carnival had been donated to the school. Health officials said that the buns, which were buttered, had apparently been left for some time at room temperature. Another possible source was a salad for which potatoes had been peeled some hours before use and which might have been handled by a carrier, according to the newspaper report.

WEST VIRGINIA

Society News.—Dr. Walter E. Vest, Huntington, addressed the Boone County Medical Society, April 20, on "Socialized Medicine and Medical Aid to the Indigent."——Drs. Lawrence B. Gang and Isidore I. Hirschman, Huntington, addressed the Logan County Medical Society April 12 on "Familial Hemolytic Jaundice" and "The Incidence and Diagnosis of Carcinoma of the Lung" respectively.——Dr. Charles J. Barone, Pittsburgh, addressed the Monongalia County Medical Society, Morgantown, in April on "Prenatal Care and Common Complications of Pregnancy."——At a meeting of the Parkersburg Academy of Medicine in April Dr. Oscar Swineford Jr., Charlottesville, Va., gave an address on "Diagnostic and Therapeutic Problems of Allergy."

WISCONSIN

Personal.—Dr. Edwin H. Federman, Montello, has been appointed health officer of Eau Claire County.——Citizens of Kimberly gave a banquet April 16 in honor of Dr. Charles G. Maes, who has practiced in the village for thirty-two years, and changed the name of the street on which he lives to Maes Avenue.

GENERAL

Division of Venereal Diseases Issues New Folder.—The division of venereal diseases of the United States Public Health Service has just issued the third in a series of educational folders dealing with syphilis which are generally available at $1 per one hundred copies. The present folder is entitled "You Can End This Sorrow," and is concerned with the prevention of syphilis in prospective mothers and in newborn babies. It is well written, concise, suitably illustrated and certainly should be in the hands of every prospective mother.

Bequests and Donations.—Gifts and bequests of more than $20,000 to the James Whitcomb Riley Memorial Association have been reported, including $16,000 from the estate of Mrs. Atta R. Linthicum, Evansville, Ind.; about $1,000 from the estate of Mrs. Emma Herpick, Indianapolis, half of a $3,500 bequest left jointly to the memorial association and the General Protestant Orphans' Association by John G. Lehr, Indianapolis, and a bequest of $8,000 from the estate of Ira Williams, Anderson, subject to the settlement of litigation brought to construe the will. It was also announced that John W. Bradford of Morgan County had given his $75,000 home and 900 acres of land to be used as a convalescent unit of Riley Hospital or for some similar purpose; the gift was made to Riley Hospital and Indiana University.

CANADA

Rural Health Conservation Awards.—The St. Jean-Iberville-Laprairie-Napierville county health unit received the first award in the second rural health conservation contest conducted by the Canadian Public Health Association in cooperation with the American Public Health Association. This four-county unit also won the award in the 1937 contest. Nine awards of merit were conferred on other units.

Government Services

Medical Phases of Social Security Administration

The Social Security Board in its report for the fiscal year ended June 30, 1938, states that the Children's Bureau of the U. S. Department of Labor made grants of $3,728,930.58 from funds provided by the Social Security Act to state and territorial agencies for maternal and child health services and $2,694,676.33 for services for crippled children.

Fifty-one plans were submitted by states and territories for maternal and child health services. More than half the funds in the fiscal year 1936-1937 were used to provide public health nurses; about 1,000 new ones have been placed in the field. Reports of state health officers for the calendar year 1937 showed that physicians made 1,405,807 health examinations of school children. Office and home visits by public health nurses included 880,691 for maternity nursing, 1,092,188 for infants, 945,616 for preschool children and 2,975,790 for school children. Reports showed 898,506 diphtheria immunizations and 1,078,779 smallpox vaccinations.

Fifty jurisdictions are now receiving funds through the Children's Bureau for services for crippled children. The total number of children on the state registers of forty-six states, Alaska and Hawaii as of June 30, 1938, was 151,909.

The U. S. Public Health Service with an appropriation of $8,000,000 for grants-in-aid has enabled states to strengthen their health organizations along the following lines: promotion and supervision of local health services, public health engineering, control of preventable diseases, laboratory facilities, dental hygiene, vital statistics and public health nursing. Thirty-three states now have special units for control of venereal disease; twenty-five have instituted measures for control of tuberculosis; eight have active programs to decrease pneumonia mortality; six others have organized an attack on cancer. More than 3,000 persons have received special graduate training in public health work.

The third agency concerned with welfare services under the social security program is the Office of Education, which administers the program for rehabilitation of the physically disabled. The roll of cases receiving rehabilitation services as of June 30, 1938, was about 45,000. The largest number of persons rehabilitated in any single year was 11,091 in the fiscal year 1936-1937.

Dust Diseases of the Lung

In a lecture to the Industrial Welfare Society Dr. Philip Ellman pointed out that in the woolen, cotton, leather and tobacco industries catarrhal infections of the lungs were observed and "cotton bronchitis" had recently received attention in Lancashire, but that there was no evidence of any serious fibrosis of the lungs resulting from exposure to such dusts. On the other hand, the inhalation of certain inorganic dusts might prove very damaging to the lung, producing progressive fibrosis. Inhalation of dust containing silica produced silicosis. In hematite miners, ferric oxide and silica produced a modified form of silicosis, termed siderosis or siderosilicosis. In contrast to the nodular fibrosis of silicosis, asbestos produced diffuse pulmonary fibrosis (asbestosis). Silicate dusts other than asbestos had not been shown to be particularly harmful. In certain cases modified forms of pneumoconiosis resulted from exposure to a mixture of free silica and silicate dusts, and metallic dusts were harmful in proportion to their percentage of free silica. Exposure to ordinary coal dust was not harmful to the lung, but the hazard depended on whether anthracite was present. Apart from anthracosilicosis, so-called miners' asthma, in which free silica dust was present, there was no evidence that ordinary coal dust rendered the miner liable to pulmonary tuberculosis. In trades in which tuberculosis was common and there was some volume of dust apart from silica and asbestos, tuberculosis was probably due to social and economic conditions.

In the discussion which followed, Prof. E. L. Collis stated that he had investigated two conditions due to cotton dust. One occurred in epidemic form among weavers, was almost certainly a mycosis and closely resembled open and early tuberculosis with pyrexia; but in all cases the condition cleared up in a month or so. The other was the chronic asthma of cotton strippers, due to dust from raw cotton. It developed after years of work and was incapacitating but did not predispose to tuberculosis.

Closure of the Ductus Arteriosus

It is usually taught that closure of the ductus arteriosus, which in the fetus carries blood from the pulmonary artery to the aorta, thus by-passing the lungs, is due to the inception of respiration, with expansion of the lungs, causing blood to pass through them from the pulmonary artery. This explanation is now challenged by an x-ray study of the ductus arteriosus in lambs made by A. E. Barclay, Sir Joseph Barcroft, D. H. Barron and K. J. Franklin and recorded in the *British Journal of Radiology*. The fetal lamb was delivered by cesarean section performed on the ewe near term. Colloidal thorium dioxide was injected into a vein, and serial pictures were taken at short intervals by x-ray cinematography over a period of half an hour. The time between delivery and the first exposure was as short as twenty-five seconds in some experiments. The ductus arteriosus was clearly shown in some of the roentgenograms, but a patent vessel was not indicated after about a minute from the time of delivery. After this it appeared as a kinked and beaded structure, and its course and caliber were seen to be continuously changing. It is suggested that these appearances are due to strong localized muscular contractions of the wall of the duct, which produce occlusion. Thus the closure could not be related to the onset of respiration or the arrest of circulation through the umbilical cord, for it took place before any air was seen in the trachea and before the cord was clamped. The origin of the stimulus to closure remains obscure. The only obvious source is alteration in the external environment.

Food Plans for Wartime

Government plans for the control and distribution of food in time of war are announced. A ministry of food would be set up and be the sole importer of all foodstuffs as well as of all home supplies as they left the farm or factory. The wholesaler would buy from the ministry at prescribed prices and the retailer from the wholesaler. It is thought that this would prevent profiteering and speculation and minimize the risks of damage and delay. Immediately on the outbreak of war about 1,400 local food control committees would be set up. Their work would be to register and license retailers and certify their requirements in regard to supplies. Committees of traders have also been set up. Their work would be to make alternative arrangements if local sources of supply should fail owing to an attack or other causes. The government already holds reserves of wheat, sugar and whale oil which can be used to tide over difficulties. For persons evacuated from their homes a forty-eight hour emergency supply would be available in the reception area.

Extensive arrangements have been made for rationing meat, butter, margarine and sugar, but a general rationing of food is thought unlikely. The necessary documents have been prepared, household application forms by which would be obtained cards to enable purchases of prescribed quantities to be made. Nineteen million application forms and sixty million ration cards have been prepared as a temporary scheme. It is expected that an improved scheme will be introduced after six months by which 20,000,000 persons would be entitled to additional rations in consequence of the class of work in which they were engaged.

Claude Bernard

A new series of publications gives selections from the works of great scientists. Jean Rostand has been entrusted with the task of presenting to the public these selections from the works of the physiologist Claude Bernard, borrowed mostly from his "Introduction to Experimental Medicine" and partly from his lectures at the Collège de France and the Muséum.

Claude Bernard was not only a just and rigorous soul; he was one of the greatest writers of the French language. His style was characterized by Renan as a "true, sober, proportioned style in whatever he has to express," simple language always clear, thought that is vigorous. Such are some of the qualities of Claude Bernard. His literary value was so adequate for his scientific will that he must always remain a great thinker, a great writer and a great scientist. He began by doing menial work in a pharmacy in Lyons and would have never revived physiology if he had not written a tragedy which he took to Paris. Nobody cared for it; he was advised to continue medicine and entered one of the laboratories of the Collège de France, where he was to occupy, later on, the chair of physiology.

It is unnecessary to summarize his discoveries. It is more to the point to consider the struggle he had to carry on against the reigning doctrine of vitalism. The "vital properties" (propriétés vitales) were considered antagonistic to or at any rate different from the natural forces (forces naturelles); living beings were not subjected to the laws governing raw bodies (corps bruts). Claude Bernard proclaimed the contrary and affirmed unity presiding over all phenomena. He demonstrated it by experimentation. Claude Bernard did not explain everything through physics and chemistry. He admitted that science has its limits.

The History of Medicine

The latest meeting of the Société internationale d'histoire de médecine was held in Paris. Medical folklore was the principal object discussed; then the program of the next meeting was adopted, to be held in Berlin in 1940 to consider the evolution of medicine from Harvey to Haller and the history of exanthematous typhus. In addition to studies on medicine and French physicians, the Société française d'histoire de la médecine and its branches have devoted much attention to the ancient Greeks and Arabs, from whom so much knowledge and tradition come. Mr. Souques, for instance, studied at length "Pain in the Writings of Hippocrates." The abundance of hippocratic documentation enabled him to group the observations of the master of Cos according to organs and functions, which makes this study most interesting.

Prevention of Epidemics

One of the most essential tasks confronting the department of organization of hygiene of the League of Nations is to prevent epidemics and their dissemination. Asia, the cradle of civilizations, is the cradle of many diseases as well: for this reason a new office has been set up at Singapore destined to centralize all useful information about epidemics and inform, as quickly as possible, the ports of the Far East about their sudden appearance. A powerful radio station at Malabar, on the Island of Java, broadcasts daily the communications of the main office in Singapore, which is rebroadcast weekly by nine secondary stations. These communications can be received in the ports of the Indian Ocean, of the Pacific and even of the Mediterranean, but for various reasons certain broadcasting stations discontinued their communications and thus several receiving stations remained without information. The Geneva office then decided to centralize these broadcasts; they will be made from Geneva weekly, on wavelengths of 16, 23 and 20, 64 meters, through the station "Radio-Nations" at 8:40 Greenwich mean time and they will be able to reach the remotest receiving sets.

Lister Medal Awarded to René Leriche

The Lister committee awards the Lister medal to a surgeon every three years. The medal displays the portrait of Joseph Lister on one side and a rising sun on the other, as though to symbolize the splendor the great Englishman has cast on his art. A reward of £500 is added to this and the sole obligation connected with receiving it is to give a lecture. Leriche is the sixth beneficiary of the Lister medal, which has been awarded up to the present to only two foreigners, von Eiselsberg and Harvey Cushing. Unquestionably the awarding committee wanted to reward in René Leriche the constant concern to raise surgery, with the aid of the sciences which are at the basis of all the branches of medicine, above a manual function and show that, although specialization is a practical necessity of our profession, it becomes dangerous if it confines the physician to a single branch of medicine.

Professor Leriche received the medal in the main assembly hall of the Royal College of Surgeons in London, where he gave a lecture entitled "The Listerian Conception in 1939."

The Bone Marrow in Recent Syphilis

Benda and Orinstein reported at the Société médicale des hôpitaux de Paris the results of investigations on thirty-five patients, of whom twenty-eight had primary and eight secondary syphilis. In addition there was one case of old syphilis. Sternal puncture was the process used. A drop of liquid bone marrow taken by puncture and mixed with an equal amount of distilled water was examined. The examination was made either after staining with fontana Tribondeau or with the ultramicroscope. On account of rigorous standards in interpretation the results obtained are rather discordant. The authors recognized the incontestable presence of the spirochetes in four cases of primary and one case of secondary syphilis; they report on the other hand six results which they qualify as "partial" and which are just as valid to them as the others. While sternal puncture is simple, it may be difficult to interpret the results. The presence of spirochetes in bone marrow was quite unexpected.

This observation may find therapeutic applications and it is of great doctrinal interest. It joins the already numerous symptoms that indicate the rapid diffusion of syphilis in the organism. Judging by the statistics of Benda and Orinstein, sternal puncture is more conclusive than ganglionic puncture: in twenty cases in which the two tests were applied, the puncture of the ganglion gave four and the puncture of the sternum six positive results.

This session of the Société médicale des hôpitaux de Paris was presided over by Pierre Lereboullet, successor to Georges Guillain in this office.

Regulations for the Use of Narcotics

In 1930 there was issued a governmental order regulating the medical prescription of narcotics (The Journal, Feb. 28, 1931, p. 706; July 1, 1933, p. 61). According to the order, physicians are prohibited from issuing narcotic prescriptions except when they are "medically justified." What was meant by the restrictive words was not explained. However, the basis of the decree of 1930 was the so-called guiding principles set up by the physicians themselves in their convention in Danzig in 1928. These principles have now been expanded and expounded by the national medical leader, Dr. Wagner, in conjunction with the department of public health. The publication of these "Regulations for the Use of Narcotics in Medical Practice" has just taken place. Medical practice will henceforth have to govern itself according to them. The physician should always bear in mind that the first morphine injection may be habit forming. The same is true of every opiate in tablet form. Special precautions are necessary in the case of weak willed or neurasthenic persons, of psychopaths and of those who can easily acquire narcotic drugs, such as physicians, nurses, druggists and their relatives. Wherever feasible the first use should be postponed as long as possible and the narcotic given in small doses. The hypodermic syringe may be intrusted to others only in exceptional cases and that to trustworthy persons acting under medical instructions. The possibility must also be considered that relatives of the patient and other persons may help themselves to the drug. Narcotic prescriptions are to be given only to those who can identify themselves.

Prescription of opiates is medically justified only if after a rigorous examination of the peculiar features of the individual disease the physician arrives at the conclusion that their use is imperative. Recurrent prescriptions are medically justified only if all other possibilities have been exhausted and if the patient is in great pain that will not yield to the usual alleviating remedies. Opiates are indispensable in assuaging exceedingly severe pains, for example in serious accidents and in painful incurable diseases. The use of opiates, the decree continues, generally is not warranted in locomotor ataxia, especially the initial stages; in bronchial asthma, only in exceptional cases; in bronchitis, almost never. Narcotics and soporifics are two different things. In heart disease, generally speaking, only individual doses of opiates are necessary; for example, in angina pectoris and cardiac asthma, after other measures have proved unsuccessful. Psychoses make the use of opiates unavoidable only in serious cases. The prescription of opiates may be necessary after careful diagnosis in grave

cases of renal and biliary calculus. The danger that the physician may be imposed on is particularly great; to furnish recurrent prescriptions simply means supporting a habit induced by previous prescriptions. Complaints of pain in amputated stumps, the extent of which is often difficult to estimate, demand a careful examination of the whole personality of the patient and his trustworthiness, especially when prescription of opiates is a standing order.

The regular prescription of opiates for addicts, in the absence of evidence that the original disease persists, is medically justifiable only if withdrawal would endanger the patient's life. Social reasons, e. g. the assertion that the patient cannot afford to interrupt his work to undergo treatment, do not justify continuance of the drug. The physician's underlying purpose in the treatment of addicts must be to plan a scientifically sound and progressive withdrawal and to supplement it with psychiatric measures. The minimal quantity of morphine indispensable in preventing serious conditions secondary to abstinence must be ascertained individually in the addict himself but independently of his statements. It is always considerably less than the quantity actually last taken by him: about one half or one third of what he alleges. The use of cocaine has already been restricted to the practice of specialists. Even here it can be replaced by one of the more recent local anesthetics which are not habit forming.

Epidemic Keratoconjunctivitis

About the middle of July 1938 there appeared in Berlin an ocular disease affecting the conjunctivae and the uppermost layers of the cornea. It was diagnosed by the university clinic as keratoconjunctivitis epidemica. The presence of the same disease was also reported from Bonn and Munich. Other parts of Germany seemed to have been unaffected. About 150 patients were clinically observed after the middle of the year. Primary indication was that resembling general influenza, followed by edematous catarrhal conjunctivitis. The bulbar conjunctiva in many cases showed vesiculation. Occasionally, small petechial hemorrhages were found. Secretion was almost never suppurative. Though the cornea and iris were not involved, patients complained of photophobia and the presence of a foreign body. Frequently there occurred a swelling of the regional lymphatic glands. After from eight to twelve days the severity of the inflammation relaxed. At this time, usually, opacity of the cornea set in, affecting mostly the center of the cornea but in evidence also in the regional portions. Dr. Smitmans connected with the clinic reported the visibility, even under weak magnification, of globular and oval, indistinctly defined, centers, which often were somewhat prominent, preponderantly intra-epithelial, without, however, penetrating to an extensive degree. In individual cases the centers appeared circular and linear and a certain connection seemed to exist between them and the epidermal nerves. The centers would then remain for a long time completely unchanged. Neither vascular proliferation of the cornea nor a severe irritation of the iris was observed. The conjunctivae were usually affected on both sides. Corneal infection was almost always noticeable, even though only a slight one. Visual acuity was generally considerably reduced at the height of the disease and in individual cases as much as 5/35 but improved after the subsidence of the acute inflammation. A slighter deterioration in visual power from 5/7 to 6/10, depending on the condition of the cornea, persisted. Generally patients of middle and advanced age were affected, sometimes also children. This outbreak was extremely infectious, spreading not only to members of the family but also to ophthalmologists, probably by exogenic transmission. Penetration to the deeper parts of the eye did not seem to occur. The incubation period apparently extended from five to seven days. Attempts to transfer conjunctival secretions to rabbits as well as intracorneal and intracerebral injections gave negative results. Treatment consisted of daily application of a 1 per cent solution of silver nitrate. This seemed to heal conjunctivitis more rapidly and to reduce corneal infection. The iris was treated with atropine; the cornea, however, could not be cleared up.

A Berlin ophthalmologist who had observed about 700 patients within this period found corneal complications in about half of them. He found opacities under Bowman's membrane and exceedingly numerous ones in the pupillary region. These hindered vision exceedingly, were exceptionably stubborn and did not begin to clear up until six or eight days after. Toward the end a more severe corneal infection in herpes form made its appearance and extended in some cases to the edges of the cornea. Singularly enough, corneal infections never appeared at the beginning of the disease but only after the acute stage had passed and the worst was believed to be over. The appearance of the disease in different sections of the business center of Berlin with its many offices and vitiated air was to be expected, in view of the many cases of chronic conjunctivitis generally found there. The infection often remained unilateral, even in serious cases.

Results of Shock Therapy in Schizophrenia

In 1933 Sakel introduced insulin and in 1934 Meduna introduced metrazol in the treatment of schizophrenia. A numerical evaluation based on a questionnaire sent by the governmental department of public health to the psychiatry clinics of the German universities yields the following figures:

Therapy	No. of Patients Treated	No. of Reporting Clinics	Symptom Free	Improved	Not Improved
Insulin	560	10	211 (37.7 per cent)	162 (28.9 per cent)	187 (33.4 per cent)
Metrazol	132	7	25 (18.9 per cent)	49 (37.1 per cent)	58 (44 per cent)
Metrazol and insulin	67	5	27 (40.3 per cent)	18 (26.9 per cent)	22 (32.8 per cent)

The official conclusions are that both of these therapies are of extraordinary value. About sixty-seven patients, equal to 56 per cent of the total number, could be regarded as favorably influenced.

The department of labor, charged with the management of the sick fund, has now ordered that metrazol therapy may be given to schizophrenic patients at the expense of the sick fund. Official permission to employ insulin therapy was granted in May 1938.

Studies on Poliomyelitis

Like other studies on the epidemic of poliomyelitis of 1937 and 1938, the pathologic studies of 1938 have now been made public. Dr. Heinlein was able to examine thirty-eight of the forty-eight cases involved. The age of the patients ranged from 6 months to 56 years. The inner organs, including the endocrine glands, showed no specific changes. The occasionally observed inflammations of the throat and tonsils were probably not sequelae but either subsequent to it or perhaps precursors of it. There were edema in the gray and white matter, hyperemia and in many cases microscopic hemorrhages, which perhaps are to be regarded as directly toxic impairments of the wall of the vessels. Frequently Clarke's columns were diseased; the lateral horns less so. The white matter, likewise, showed specific changes; only the dorsal portions of the medulla oblongata and pons were diseased. The base of the pons was always free from disease. In the cerebellum regularly changes were found, especially in the region of the dentate nucleus. These might explain appearances of ataxia, unless

the injury of Clarke's column was responsible for them. In two patients clinically spastic phenomena were most prominent, with negligible anatomic changes in the myelon but serious ones in the medulla oblongata, pons and telencephalon. In a few cases a predominantly cerebral form of poliomyelitis seems to have existed.

POLAND

(From Our Regular Correspondent)

Warsaw, May 1, 1939.

Action of Mercurial Diuretics

Dr. J. Fliederbaum has reported his research performed at the university clinic of Warsaw on the action of mercurial diuretics. Among fifty patients there were thirty with cardiac edema and nine with edema of extracardiac origin. He studied the effect of mercurial diuretics on the protein and carbohydrate metabolism and acid-base equilibrium of the blood, and the influence on excretion of water, salt, phosphates and nitrogen by the kidneys. Simultaneously the influence on the blood volume and on the functions of the reticulo-endothelial system was examined. On the basis of these examinations the author divided the action of the mercurial diuretics into three periods.

In the first period the water balance is not yet influenced by the drug and no diuretic action is observed. There appear however important changes in the distribution of blood and of tissue fluid and in the chemical composition of the blood. The absorption of saline solution injected into the skin diminishes. The return of the tissue fluid into the blood vessels increases, causing a marked rise in the circulating blood volume. In this period there is also observed an increase in the acid secretion by the stomach, in lung ventilation, in carbon dioxide excretion and in oxygen consumption; also the respiratory quotient and the level of the blood sugar undergo noticeable changes. Injected dye is to a less extent absorbed by the reticulo-endothelial system.

The second period begins with the onset of diuresis. This period the author divides into two parts. In the first the kidney threshold for water and salt excretion drops, and these substances are excreted in great amounts by urine, while the threshold for excretion of other substances, especially phosphates and nonproteinic nitrogen, increases in spite of the rise in their blood level.

In the second part of the second period the mercurial diuretics provoke a destruction of the tissue proteins. The level of nonprotein nitrogen in blood increases sometimes very much. This is accompanied by an increased excretion of water by extrarenal ways, chiefly by the lungs and the skin. Such increase in extrarenal water secretion occurs also in other conditions in which there is a toxic destruction of tissues, e. g. animals after experimental extirpation of the adrenal glands. In the toxic period of action of the mercurial diuretics many patients, especially those who for a long time have received the drug, complain of uremia-like symptoms due to intoxication with the products of destruction of tissue proteins: weakness, headache, nausea and psychic depression.

In the third period all the foregoing changes recede. However, the sensitiveness of the organism to repeated administration of diuretics remains diminished.

In patients with chronic circulatory failure the mercurial diuretics produce a deacidifying influence on the organism: there is increase in the stomach acid secretion, the carbon dioxide excretion by the lungs, the urinary acidity and the basic reserves of the plasm.

Genesis of Reticulocytes

Drs. F. Goebel and S. Marczewski reported before the Warsaw Medical Society their results of research on the genesis of reticulocytes performed in the Institute of Experimental Pathology of Warsaw University. They noticed that the erythrocyte and reticulocyte counts increase in dogs which are exposed to a low atmospheric pressure for a short time (sixty seconds). This phenomenon does not occur in splenectomized dogs. Other factors which induce a contraction of the spleen, such as intravenous injection of epinephrine or bleeding, also cause a prompt increase in the reticulocyte count of the blood. This rise after the administration of the same agents does not occur in splenectomized dogs. From these facts it can be assumed that reticulocytes as well as old erythrocytes are retained in the spleen. Thus the authors say that the reticulocytes are not young red cells, as has been commonly thought. This view is also confirmed by some clinical observations. So the reticulocytosis encountered in hemolytic jaundice can be regarded as a result not of blood regeneration but of increased erythrocyte destruction in the spleen. The reticulocytosis observed after blood transfusions can also be caused by an increased destruction of the introduced foreign red cells.

Bactericidal Action of Saliva

In the State Institute of Hygiene at Warsaw, research was performed by Dr. A. Lande concerning the germicidal action of human saliva. The results to some extent confirm the formerly known fact that saliva contains a bactericidal body, called inhibin, which hampers the growth of micro-organisms. This factor cannot be passed through the Chamberland filter. It is nonspecific, for it is active against many species of microbes. Nor is it identical with the lysozyme found in saliva by Flemming, for it does not resist heating to 56 C.

The author performed further research on the immunologic importance of inhibin. He examined the saliva of 152 subjects, among whom were 100 children from an orphanage, all of whom since their birth have lived together and have been about equally exposed to infections. There was a close relation between the morbidity from infectious diseases due to micro-organisms in the mouth and pharynx, and the frequency of the presence of inhibins in saliva. Inhibin was present in only 5.33 per cent of the subjects who gave a history of repeated anginas, diphtheria or scarlet fever or had chronic tonsillitis, while in subjects who had never been ill with these diseases the percentage of having inhibin in saliva was 38 46.

The epidemiologic importance of inhibins is more obvious as far as the morbidity with diphtheria alone is concerned. They were found neither in diphtheria carriers nor in any subject who had ever had diphtheria. It was also found that the presence or absence of inhibin in saliva is independent of serologic immunity.

The author says that the bactericidal factors of saliva are the first barrier set against infection. Besides inhibin the human saliva contains also other germicidal bodies, such as yeast.

Marriages

JOHN HAMPTON MILLER, Thomas, W. Va., to Miss Frances Taylor of Bridgewater, Mass., March 19.

RANDALL G. SPRAGUE, Rochester, Minn., to Miss Anne Whitcomb of Grand Forks, N. D., April 8.

GEORGE WILLIAM LAWSON, Star, N. C., to Miss Edna Ann Thomas of Jonesboro, April 29.

HOWARD LEE SMITH to Miss Jean Harriett Goss, both of Washington, D. C., March 4.

DONALD R. BRUMLEY, Macomb, Ohio, to Miss Helen Huntley of Davenport, Iowa, May 13.

WILLIAM GARBE to Miss Lorna Levey, both of Toronto, Ont., Canada, May 7.

WARREN W. YOUNG to Miss Dorothy Johnson, both of Chicago, May 6.

JOSE M. FERRER JR., to Miss Mary Schumacher, both of New York, June 6.

Deaths

Lee Harrison Mettler, Hubbard Woods, Ill.; Jefferson Medical College of Philadelphia, 1886; professor of neurology, emeritus, at the University of Illinois College of Medicine, Chicago; prosector and assistant to the chair of anatomy, 1886-1887, chief of the medical clinic, 1887-1891, lecturer and clinical instructor of mental and nervous diseases and electrotherapeutics, 1888-1891, Medico-Chirurgical College of Philadelphia; formerly secretary of the Chicago Neurological Society; attending neurologist to the Cook County Hospital, Chicago, 1904-1906, and Norwegian Lutheran Deaconess Home and Hospital, Chicago; author of "Treatise on Diseases of the Nervous System," published in 1905; aged 75; died, March 20, in the Highland Park (Ill.) Hospital.

Menzies John MacFarlane ⊕ Cedar City, Utah; Jefferson Medical College of Philadelphia, 1913; past president of the Utah State Medical Association; past president of the county board of education and member of the state board of education; on the courtesy staff of the Iron County Hospital; aged 57; died, March 24, at the Dr. W. H. Groves Latter-Day Saints Hospital, Salt Lake City, of a streptococcic infection of the throat with complications.

Levin H. A. Nickerson, Quincy, Ill.; University of Pennsylvania Department of Medicine, Philadelphia, 1874; member and past president of the Illinois State Medical Society; past president and secretary of the Adams County Medical Society; member of the House of Delegates of the American Medical Association, 1908-1909; aged 88; died, March 13, in St. Mary's Hospital.

Victor H. Marchand ⊕ Haubstadt, Ind.; University of Louisville (Ky.) Medical Department, 1883; Jefferson Medical College of Philadelphia, 1884; past president of the Gibson County Medical Society; bank president; aged 76; died, March 19, in the Welborn-Walker Hospital, Evansville, of injuries received in an automobile accident.

Edward Vincent Murphy ⊕ Newport, R. I.; College of Physicians and Surgeons, Baltimore, 1899; township health officer; past president of the Newport County Medical Society; formerly connected with the United States Public Health Service; on the staff of the Newport Hospital; aged 68; died, March 9, of cerebral hemorrhage.

Charles Higgins Cole, Binghamton, N. Y.; Albany (N. Y.) Medical College, 1894; member of the Medical Society of the State of New York; for many years superintendent of the Tuberculosis Hospital of the County of Broome, Chenango Bridge; aged 68; died, March 24, of diabetes mellitus and mesenteric thrombosis.

Leo Alexander Newcomb, Montpelier, Vt.; University of Vermont College of Medicine, Burlington, 1901; member of the Vermont State Medical Society; past president of the Washington County Medical Society; served during the World War; aged 62; on the staff of the Heaton Hospital, where he died, March 3.

Charles Alexander Martin, Amherstdale, W. Va.; University of Louisville (Ky.) Medical Department, 1908; member of the West Virginia State Medical Association; past president of the Logan County Medical Society; aged 59; died, March 25, of hypertensive heart disease with myocardial insufficiency.

W. H. Post, Masontown, W. Va.; Baltimore Medical College, 1901; member of the West Virginia State Medical Association; at one time superintendent of the Hopemont (W. Va.) Sanitarium; formerly member of the school board; aged 61; died, March 18, in the Monongalia County Hospital, Morgantown.

Harold Oliver Lund, Middletown, Ohio; University of Minnesota Medical School, Minneapolis, 1922; member of the Ohio State Medical Association and the American Academy of Pediatrics; served during the World War; on the staff of the Middletown Hospital; aged 41; died, March 6, of heart disease.

John Franklin Dunseith, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; member of the Medical Society of the State of New York; formerly member of the health department; aged 63; died, March 6, at New Rochelle of angina pectoris.

Wilbur Thomas Myers, Uniontown, Pa.; University of Louisville (Ky.) Medical Department, 1909; member of the Medical Society of the State of Pennsylvania; also a pharmacist; aged 55; died, March 2, of diabetes mellitus, rupture of the femoral artery and colon and septicemia.

John Isaac Becker, Poughkeepsie, N. Y.; Syracuse University College of Medicine, 1905; member of the Medical Society of the State of New York; aged 68; died, March 13, in the Vassar Brothers Hospital of carcinoma of the mediastinum and obstruction of the esophagus.

John Howard McCulloch ⊕ Beckley, W. Va.; University College of Medicine, Richmond, 1908; medical superintendent of the Beckley Hospital; fellow of the American College of Surgeons; aged 53; died, March 18, of a skull fracture received in a fall down the stairs.

Jasper Victor Howard ⊕ Medical Inspector, Commander, U. S. Navy, San Francisco; University of Pennsylvania School of Medicine, Philadelphia, 1909; fellow of the American College of Surgeons; entered the navy in 1910; aged 56; died, March 12, of heart disease.

Gerald James A. Dolan, Brooklyn; Georgetown University School of Medicine, Washington, D. C., 1938; aged 26; intern at St. Mary's Hospital, where he died, March 2, of embryogenic carcinoma of the right testicle with metastasis to the abdomen, lung and brain.

Hugh Herald Miltimore ⊕ St. Johnsbury, Vt.; University of Vermont College of Medicine, Burlington, 1907; past president and secretary of the Caledonia County Medical Society; on the staff of the Brightlook Hospital; aged 55; died, March 1, of angina pectoris.

Charles H. W. Auel, Buffalo; University of Buffalo School of Medicine, 1886; member of the Medical Society of the State of New York; for many years on the staff of the Memorial Hospital; aged 75; died, March 16, of chronic myocarditis and cerebral hemorrhage.

James Carl Minor, Long Beach, Calif.; University Medical College of Kansas City, Mo., 1891; member of the Missouri State Medical Association; fellow of the American College of Surgeons; aged 69; died, March 24, of heart disease.

Lewis De Witt Hews, Rockwell City, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; aged 62; died, March 25, in Des Moines of carcinoma of the sigmoid colon and peritonitis.

Robert Eugene Miller, Lansing, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890; member of the Michigan State Medical Society; aged 70; died, March 1, of cardiovascular renal disease.

Francis Cicero McDowell ⊕ Siler City, N. C.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; aged 65; died, March 14, in the Piedmont Memorial Hospital, Greensboro, of influenza and pneumonia.

Alvah Smith McClain, Kansas City, Mo.; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1898; served during the World War; aged 72; died, March 10, of coronary thrombosis.

Laurence Joseph Murphy, Evanston, Ill.; University of Illinois College of Medicine, Chicago, 1931; member of the Illinois State Medical Society; aged 31; died, March 17, in St. Petersburg, Fla., of chronic nephritis.

William Preiss, Buffalo; Niagara University Medical Department, Buffalo, 1895; member of the Medical Society of the State of New York; aged 68; died, March 3, of coronary thrombosis and arteriosclerosis.

Harold Lewis Bollig ⊕ Los Angeles; University of Nebraska College of Medicine, Omaha, 1929; on the staff of the Methodist Hospital of Southern California; aged 36; died, March 21, of lobar pneumonia.

Charles De Forest Lucas, Charlotte, N. C.; University of Virginia Department of Medicine, Charlottesville, 1926; member of the American Radium Society; aged 40; died, March 13, of lymphosarcoma.

Earl Victor Bobb, Alhambra, Calif.; Northwestern University Medical School, Chicago, 1899; member of the American Academy of Ophthalmology and Oto-Laryngology; aged 64; died, March 4.

Henry West Hughes, Los Angeles; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885; aged 80; died, March 15, in the Hospital of the Good Samaritan.

John Dane, Boston; Harvard University Medical School, Boston, 1892; member of the Massachusetts Medical Society; formerly instructor in orthopedics at his alma mater; aged 72; died, March 27.

John Wesley Mullin, Wilmington, Del.; Hahnemann Medical College and Hospital of Philadelphia, 1886; on the staff of the Homeopathic Hospital; aged 73; died, March 2, of pneumonia.

William E. Miller ⊕ Chicago; College of Physicians and Surgeons of Chicago, 1887; on the staff of the Hospital of St. Anthony de Padua; aged 81; died, March 25, of uremia and nephritis.

Luther Francis Kepler, Cedar Rapids, Iowa; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1904; aged 58; died, March 1, of uremia, nephritis and hypertension.

Jasper Eugene Neighbors ⊕ Hobbs, N. M.; University of Arkansas School of Medicine, Little Rock, 1918; formerly on the staff of the Hobbs General Hospital; aged 52; died, March 22.

Frederick Randolph Abbe ⊕ Boston; Harvard University Medical School, Boston, 1895; medical director of the Loyal Protective Life Insurance Company; aged 70; died, March 2.

Archie Schuyler Brown, Indianapolis; Medical College of Indiana, Indianapolis, 1904; served during the World War; on the staff of the Methodist Hospital; aged 62; died, March 12.

Thomas P. McCullough, Detroit; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1888; aged 78; died, March 2, of chronic endocarditis and bronchial asthma.

Norman Henry McCrummin, Montgomery, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1884; aged 85; died, March 26, of hypostatic pneumonia.

Harry Mandel ⊕ Chicago; General Medical College, Chicago, 1923; aged 41; on the staff of the Englewood Hospital, where he died, March 15, of coronary thrombosis.

Charles Lafleur, Montreal, Que., Canada; Laval University Medical Faculty, Montreal, 1908; for many years physician for the fire department of Montreal; died, March 31.

James Johnston Fraser, Hamilton, Ont., Canada; University of Toronto Faculty of Medicine, 1902; on the staff of the Ontario Hospital; aged 62; died, March 30.

Everett Rexford Myles, Windsor, Ont., Canada; University of Toronto Faculty of Medicine, Toronto, 1924; aged 49; died, February 26, in the Grace Hospital.

George Lewis Megargee, Larchmont, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1901; aged 65; died, March 4, in Altamonte, Fla.

Harriet S. MacBeth, Fort Wayne, Ind.; Fort Wayne College of Medicine, 1893; aged 66; died, March 18, of diabetes mellitus, arteriosclerosis and heart disease.

Luther Edwards, Finley, Tenn.; Memphis Hospital Medical College, 1906; member of the Tennessee State Medical Association; aged 59; died, March 31.

Howard P. Johnson, Cortland, N. Y.; Hahnemann Medical College of Philadelphia, 1881; aged 83; died, March 4, of arteriosclerosis and cerebral edema.

Elizabeth Rabb Beatty, Lansdowne, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1884; formerly a medical missionary; died in March.

James Alvin Cannon, Pickens, S. C.; Southern Medical College, Atlanta, Ga., 1881; county physician; aged 85; died, March 24, of cerebral hemorrhage.

George Ernest Myers, Cheshire, Conn.; University of Vermont College of Medicine, Burlington, 1896; aged 71; died, March 25, of coronary thrombosis.

William Albert Harvey, Berryville, Ark.; St. Louis University School of Medicine, 1909; aged 55; died, March 15, of arteriosclerosis and myocarditis.

Walter N. Boyer, Culver City, Calif.; Hahnemann Medical College and Hospital, Chicago, 1881; aged 80; died, March 2, in a hospital at Los Angeles.

Samuel John MacLennan, Windsor, N. S., Canada; Bellevue Hospital Medical College, New York, 1894; served during the World War; died recently.

Fanny Searls Gradle, Santa Barbara, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1877; aged 87; died, May 24.

William Stanley Hill, Pelham, Ga.; Atlanta Medical College, 1892; aged 72; died, March 7, of cerebral hemorrhage, nephritis and arteriosclerosis.

Carlos M. Garza, *Lampazos, Nuevo Leon, Mexico;* Universidad Nacional Facultad de Medicina, Mexico, D. F., 1888; aged 79; died, March 5.

Robert De Vean Gilman, Beverly Hills, Calif.; New York Homeopathic Medical College and Hospital, New York, 1915; aged 45; died, March 20.

John L. Stephenson, Santa Ana, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1895; aged 81; died, March 20.

James Clarke McClester, Harrisville, Ohio; Ohio Medical University, Columbus, 1894; served during the World War; aged 70; died, March 23.

Christopher W. Stoll, Dover Center, Ohio; Western Reserve University Medical Department, Cleveland, 1893; aged 70; died, February 17.

Joseph Graeme Foster, Ottawa, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1923; aged 40; died, February 22.

Frank R. Farrell, Milwaukee; Milwaukee Medical College, 1905; aged 68; died, March 16, in St. Anthony's Hospital of angina pectoris.

Holly W. Casto, Ravenswood, W. Va.; Starling Medical College, Columbus, 1896; aged 66; died, March 22, of cardiorenal insufficiency.

Willis Benton Cauble, Murphysboro, Ill.; Rush Medical *College, Chicago, 1888; aged 72; died, March 10, in San Francisco* of uremia.

Joseph E. Beck, Carmel, Calif.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1887; aged 76; died, March 2.

Charles T. Gustin, Denver; Detroit College of Medicine, 1897; also a pharmacist; aged 67; died, March 23, of myocarditis and influenza.

John Proudfoot, Monkton, Ont., Canada; Western University Faculty of Medicine, London, 1888; aged 75; died, February 28.

York Patchen, Westfield, N. Y.; Western Reserve University Medical Department, Cleveland, 1886; aged 77; died, February 21.

Harry L. Vradenburg, Plattsmouth, Neb.; Hahnemann Medical College and Hospital, Chicago, 1886; aged 85; died, February 19.

Wardlaw Ewell, Crawfordsville, Ind.; Kentucky School of Medicine, Louisville, 1891; aged 72; died, March 12, of cerebral hemorrhage.

John Patrick Matthews, Leesburg, Ala.; University of Tennessee Medical Department, Nashville, 1879; aged 85; died, March 10.

Tillman Brooks Bradford, Toone, Tenn.; Vanderbilt University School of Medicine, Nashville, 1892; aged 73; died, March 15.

Henry Herbert Baker, Cairo, Ill.; University of Louisville (Ky.) Medical Department, 1907; aged 58; died, March 22, of influenza.

Hector Roy, Montreal, Que., Canada; Victoria University Medical Department, Coburg, Ont., 1890; aged 75; died, February 21.

John Breckinridge Woodville, Lansing, W. Va.; Medical College of Virginia, Richmond, 1897; aged 69; died, February 14.

Russell James Smith, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1892; aged 69; died, February 12.

Brenton Johnson Hazlewood, Oshawa, Ont., Canada; Trinity Medical College, Toronto, 1899; aged 64; died, February 17.

John C. Cunningham, Hixson, Tenn.; Chattanooga Medical College, 1898; aged 71; died, March 28, of cerebral hemorrhage.

Ira Albert Freel, Stouffville, Ont., Canada; University of Toronto Faculty of Medicine, 1882; aged 78; died, February 20.

Alvah D. Decker, Staten Island, N. Y.; Long Island College Hospital, Brooklyn, 1876; aged 90; died, February 15.

Thomas Arthur Ellis, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1920; aged 59; died, March 21.

James Piner Bartley, Duncan, Okla.; Kentucky School of Medicine, Louisville, 1898; aged 72; died in February.

Charles W. Tufts, Wyoming, Ohio; Medical College of Ohio, Cincinnati, 1884; aged 83; died, February 15.

Morris Barrett, Maidens, Va. (licensed in Virginia in 1885); aged 76; died, March 10.

Levi S. Correll, Jacksonville, Fla. (licensed in Illinois in 1878); aged 93; died, March 3.

Bureau of Investigation

THE VITA COMPANY FRAUD

A Chicago Mail-Order Quackery Debarred from the Mails

A small but dangerous medical mail-order fraud was debarred from the mails on Sept. 2, 1938. It was conducted from Chicago and, according to a memorandum of the Acting Solicitor for the Post Office Department to the Postmaster General, was carried on by one Chester A. Cremin and his wife. These persons advertised and sold through the mails a preparation called "Vita Vaginal Suppositories," which they claimed were a treatment for suppressed or excessive menstruation, "whites," vaginitis, inflammation and tumors of the uterus, as well as for displacements and prolapse of that organ.

The business was said to have been started about forty-three years ago by Mr. Cremin's mother. While Cremin was said to have declared that he was the sole owner of the business, the federal authorities charged that Cremin's wife actually conducted the business. The files of the Bureau of Investigation of the American Medical Association contain an advertising leaflet issued in 1929 and entitled "Vita Means Life for Ladies."

It was put out by The Vita Company (Not Inc.) at 8237 Maryland Avenue and 1039 East Eightieth Street, Chicago, "Mrs. C. A. Cremin, Mgr." At that time the Vita Company listed some sixteen diffent preparations, of which Vita Vaginal Suppositories seemed to be the major opus, although there was also a "Vita Catarrah [sic] Ointment" on the list.

The Cremins are said to have told the Post Office inspectors that the vaginal suppositories contained lanolin, vaseline, cocoa butter, ichthyol, alum and borax. The government chemists found that they actually consisted of boric acid, Glauber's salt, petrolatum and lycopodium. As neither combination could by any stretch of the imagination cure the conditions set forth in the advertising, and moreover, as sole reliance on this "patent medicine" might in certain cases lead to serious illness or even death, the scheme was declared a fraud and on Sept. 7, 1938, the mails were closed to the Vita Company and to Mrs. C. A. Cremin, Mgr.

AN OBESITY CURE FRAUD

The Gessner-Laun Swindle Barred from the Mails

The United States mails have been closed to a mail-order fake known as "Dr. Laun Sales Co.," doing business from 207 North Michigan Avenue, Chicago. The information that follows is based on a memorandum by the Hon. W. E. Kelly, Acting Solicitor for the Post Office Department, to the Postmaster General, and also on material in the files of the Bureau of Investigation of the American Medical Association.

The business was conducted by one Joseph E. Gessner, who sold through the mails a preparation called "Dr. Laun's Stimulating and Reducing Balm." This preparation, according to Gessner, would, when rubbed on the body by obese persons, make fat "melt away like magic." The name of Gessner appears previously in the files of the Bureau of Investigation of the American Medical Association. In July 1937 J. E. Gessner of 207 North Michigan Avenue, Chicago, was reported

by the Federal Trade Commission to have agreed "to discontinue false and misleading advertising" in connection with the sale of an alleged treatment for piles.

When the government chemists analyzed Dr. Laun's Reducing and Stimulating Balm they found the nostrum to consist essentially of alcohol, water, camphor, tragacanth and epsom salt. Of course, rubbing such a mixture on the skin of a stylish stout would not reduce her weight—especially if she followed Gessner's suggestion that she "eat 3 square meals daily."

On Sept. 1, 1938, a fraud order was issued, closing the mails to Dr. Laun Sales Co. and its officers and agents as such.

On June 15, 1939, the Federal Trade Commission released stipulation No. 2480:

Joseph E. Gessner, trading as Dr. Laun Sales Company, 207 North Michigan Ave., Chicago, agrees to cease disseminating advertisements representing that "Dr. Laun's Reducing and Stimulating Balm," either with or without the application of massage, will remove fat from the body or any part thereof or that the preparation or any of its ingredients has any value as a reducing agent.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Glandeen Tablets.—Lucky Heart Laboratories, Inc., Memphis. Composition: Extracts of plant drugs including damiana and nux vomica, with iron carbonate, coated with chalk and sugar. Fraudulently represented as a "powerful strength invigorator," to restore lost vitality or "lost manhood," etc.—[*N. J. 28311; September 1938.*]

Preacher's No-Ru Kidney Bladder Rheumatism Backache Remedy.—Lucky Heart Laboratories, Inc., Memphis. Composition: Essentially small amounts of potassium acetate, methenamine and extracts of plant drugs, with sugar and water. Fraudulent therapeutic claims.—[*N. J. 28311; September 1938.*]

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

POSTOPERATIVE PULMONARY COLLAPSE

To the Editor:—What is the best method of treating the following postoperative complication in the chest: A day or two after operation the chest fills up with bubbling rales, which may be audible at the foot of the bed. The respirations are accelerated and there is some peripheral cyanosis. The temperature is elevated (from 101 to 102 F.). A rasping wheeze is audible and a cough, which may be productive of a thick, tenacious, greenish yellow sputum, is present. Examination of the chest reveals only large bubbling rales (the appearance is similar to that seen in pulmonary edema). There is no evidence of consolidation. This complication has frequently occurred in my cases postoperatively. The last one was in a man aged 74 who had had a suprapubic cystotomy done under local anesthesia. He showed no evidence of any latent or evident cardiac condition or respiratory disorder prior to operation.

M.D., New York.

ANSWER.—The condition described suggests postoperative pulmonary collapse followed by temporary failure of the circulation, or perhaps the latter condition alone. The large bubbling rales may be caused by secretions in the larger bronchi or may indicate the presence of pulmonary edema.

If atelectasis is the cause, prevention is more important than treatment. After operation the patient should not be deeply narcotized; cough, unless excessive, should not be too greatly suppressed, and tight binders should not be placed about the chest or abdomen. The patient's position in bed should be changed frequently. Collections of secretion in the pharynx or larynx should be aspirated with a suction apparatus. It is important to keep the patient warm and well but not excessively supplied with fluids.

If atelectasis has already occurred, the patient should be rolled from side to side occasionally or should lie with the affected side up to facilitate drainage of secretion. Bronchoscopy and aspiration may be tried. A mixture of oxygen and 5 per cent carbon dioxide should be given by inhalation if the patient will not or cannot voluntarily breathe deeply. Oxygen therapy by nasal catheter or tent may relieve the tachypnea and cyanosis. If pulmonary edema is present, fluids should be restricted. Digitalis and so-called cardiac stimulants such as camphor or strychnine have no place in the treatment of this condition. Hypodermic injection of atropine sulfate 1.3 mg. (1/50 grain) and solution of epinephrine hydrochloride U. S. P. 0.5 cc. (8 minims) may aid in clearing the lungs of bubbling rales but may increase the tachycardia.

ASTHMA IN SMALL BOY

To the Editor:—A boy aged 3 years 4 months, has severe asthma. He is sensitive to a few foods as shown by skin tests, but avoidance of these foods does not eliminate the wheezing. He is not sensitive to any of the epidermals or pollens. However, his asthma is worse at night and when the wind is from the west. I would appreciate any help you could give me on further diagnosis or treatment. M.D., Illinois.

ANSWER.—The information given is insufficient for making even a tentative conjecture regarding the diagnosis. In general it may be said that infection seldom plays an important part as a primary cause of asthma in this age group. The important causes are the inhalants and the foods. A careful history is of utmost importance in the diagnosis. Such a history is more valuable if it is based on the attempt of interpretation of the various attacks over a period of months or longer.

Among the important factors to be studied are the seasonal or perennial nature of the complaint or exacerbations during any particular period of the year, the environmental contacts, as the furnishings of the bedroom, feathers, cottonseed (mattress), wool, toys and animal contacts, the environmental contacts in the rest of the house, occupational contacts of the parents, and environmental contacts about the house: factories, stables, barns. If it is confirmed by repeated observation that perennially the patient is worse when the wind blows from the west, what is located at a reasonable distance west of the home? If this effect is seasonal, pollen should be suspected.

The question of foods as a possible cause of the condition should be studied by means of a diet diary or elimination diet, as described in any of the current textbooks on allergy (Rowe, Tuft, Rackemann or Coca).

Regarding the negative skin reactions obtained, it is not indicated in the inquiry whether the tests were done by cutaneous or intracutaneous technic. The skin reactions at this age are, next to the history, of greatest importance. They are usually positive at this age but may require the intracutaneous technic for demonstration. Unless they have been performed in this manner, with materials known to be active, it cannot be said that the reactions were negative to the inhalants or pollens.

In cases in which these suggestions have been carried out without results, the room should be furnished in a manner to eliminate all environmental substances known to produce atopy. This may be done by encasing the pillows and mattress with rubberized material, sealing all seams. The furniture should not be upholstered but should consist of wood or cane, with no pads. Such substances as orris root, animal danders and wool (carpets, blankets) must be eliminated. Draperies and other accessories likely to gather dust should be removed. The child may then be kept in this room and clinical studies made by introducing the various suspected substances into the room one at a time during asthma free periods and the effects observed.

These are but a few suggestions for such study. Some of these problems are sufficiently difficult to defeat the efforts of the most carefully trained physician. However, the more one studies the history, the more likely will the result be successful.

POSSIBLE ARSENICAL HEPATITIS

To the Editor:—A white man aged 42, examined April 24, 1937, showed Kahn, Wassermann, Hecht-Gradwohl Wassermann and Laughlen tests positive 4 plus. A series of seventeen neoarsphenamine and seventeen bismuth injections were given, with severe reactions to the neoarsphenamine developing. These were followed by ten thio-bismol, six mapharsen, six bismuth and three tryparsamide injections. Because of severe reactions all arsenicals were discontinued in November 1937. Between that date and March 1939, forty-six injections of 0.2 Gm. of thio-bismol were given. Sept. 22, 1937, the Wassermann reaction was 4 plus and December 1 the Kahn reaction was 3 plus. Jan. 9, 1938, spinal puncture showed the colloidal gold curve negative, the Kahn reaction 2 plus, the Kline reaction 2 plus and the Rytz reaction negative. In September 1938 the blood Kolmer reaction was 3 plus. November 8, urinalysis was negative. The red blood count was 4,200,000, white blood count 10,400, hemoglobin 85 per cent, polymorphonuclears 75 per cent, lymphocytes 24 per cent. The Kahn reaction was 1 plus, cholesterol antigen 4 plus; Wassermann reaction weakly positive. Blood sugar was 94, blood urea 11, the icterus index 23, cholesterol 246, esters 132, 54 per cent. Total protein was 6.6, albumin 5.8, globulin 0.8, A/G 7.2. Spinal puncture gave a cell count of 0, globulin trace. The Levinson reaction was negative, colloidal gold curve 0000000000, cholesterol antigen and Wassermann reaction negative. Feb. 11, 1939, the bromsulphalein test resulted in less than 1 per cent retained in thirty minutes. With the galactose tolerance test, 0.5 Gm. was recovered in five hours. The icterus index was 6 as measured by extracting the serum with three volumes of absolute alcohol, refrigerating two hours, centrifuging and comparing with the dichromate standard. The physical examination at this time is entirely negative, with the exception of the slight jaundice. Is this jaundice, remaining fifteen months after the last dose of arsenic, due to arsenical hepatitis? What treatment is advisable at this time? HENRY G. HADLEY, M.D., Washington, D. C.

ANSWER.—The data supplied in this inquiry do not permit a definite answer of the questions asked. The reported tests of liver function are all within normal limits, so that it would seem advisable to have a serum bilirubin estimation made and at the same time determine the amount of carotene in the blood. It might be that the patient's color is not due to jaundice.

If the serum bilirubin estimation is within normal limits, further treatment for the syphilis should be limited to two courses of bismuth compounds during the coming twelve months, ten injections to the course, and after that further treatment for syphilis would seem inadvisable irrespective of the blood serologic reports. Special examination for evidence of syphilitic disease of the aorta and periodic reexaminations each six months should be made.

If the serum bilirubin indicates the presence of jaundice, the inference is then possible that the patient has had some liver damage, probably from the arsenic, in which case all treatment for syphilis should be stopped. A high sugar and a low protein diet with reexamination every month or six weeks would be advisable. Most of the patients with postarsphenamine jaundice recover completely; if, however, the continued use of heavy metal such as bismuth does not help the involution, treatment for syphilis in such cases should be discontinued.

CEREBROSPINAL VASCULAR SCLEROSIS OR THE TABETIC FORM OF DEMENTIA PARALYTICA

To the Editor:—A white man aged 79 complains of incontinence and inability to walk. He has had some weakness during the past year. Two months ago he suddenly lost the ability to get up from a sitting position and was unable to walk unassisted. In bed at that time he became incontinent. After about a month he regained some control of the bladder and could walk without assistance. At no time has he been paralyzed. Muscle power seemed normal. He got along fairly well for several weeks, only to become bedridden again with the same complaints. The patient is unable to stand unassisted; his speech is disoriented occasionally and the family reports an antagonistic accusation attitude. All arm and leg muscles have normal power and there is no paralysis of the facial or any other muscles. There are no tremors. The radial reflex is the only positive reflex. Abdominal, biceps, patellar and plantar reflexes are normal. There is no clonus. Pressure, pain and temperature sense are intact. He is blind in the left eye. The right eye has a purulent discharge and remains closed for the most part, with only slight vision. He has had chronic ulceration in the nasal corner of the right eye for sixteen years. The fundi cannot be examined owing to lack of cooperation; the disks cannot be seen; the entire fundus seems red; the vessels are hard to discern. The patient complains of pain in the epigastrium and over the precordium. The blood pressure is 160 systolic, 80 diastolic; the pulse is 72, heart sounds are faint, only the aortic sounds being audible, and are normal, and there is no evidence of arteriosclerosis in the palpable arteries. There is tenderness in the epigastrium. The patient has no desire for food. I have not yet received an answer as to his Wassermann reaction. Would you discuss this case with the probable diagnosis or further aids to a proper diagnosis?

M.D., Maryland.

ANSWER.—From the history, which has a number of variable and unusual combinations of signs and symptoms, two conditions are suggested: One is cerebrospinal vascular sclerosis and the other is the tabetic form of dementia paralytica. If there is normal muscle power, there must be some evidence of defects of deep sensibility such as sensory ataxia and abnormality of bone and joint position and vibration sense. If the latter is present the patient has cerebrospinal syphilis of the tabetic type. It is possible and probable that the patient also has cerebral and spinal arteriosclerosis. This may result in a picture of pseudobulbar palsy. It is suggested that the following be done: reexamine the patient for sensory defects such as bone and joint position, vibration, touch, pain and temperature functions; dilate the pupils and examine the optic nerve heads. If there is a primary optic atrophy one can be fairly confident that one is dealing with the tabetic form of dementia paralytica. However, if retinal sclerosis is found with secondary atrophy the patient has arteriosclerotic atrophy causing the blindness. A cystoscopic examination should be done to determine the presence of a cord bladder. What is meant by disorientation in speech? Does the man have motor or sensory aphasia or both? The latter usually occurs in arteriosclerotic and hypertensive diseases of the brain and rarely if ever in the tabetic form of dementia paralytica.

ABSENT TEETH

To the Editor:—I was interested in a query headed "Absent Teeth and Delayed Dentition in Baby" in THE JOURNAL, February 25, page 766, because of the patient I saw at my office about this age. The child was brought in with the same complaint. Physical examination was negative in every way except for the absence of eyelashes and teeth. Because of the unusually narrow gingival margin, I took roentgenograms of the jaws and found the presence of only four tooth buds. That was five years ago, and since then the child has shown the presence of only four teeth. I am wondering whether the case presented to you by the doctor from Virginia is similar in character. In looking up the literature I found no case in which the absence of teeth has been diagnosed before the appearance of some of the teeth, but in the English literature there are a few cases reported which were discovered after the eruption of some of the teeth.

ABBOTT L. WINOGRAD, M.D., Nashua, N. H.

ANSWER.—The child mentioned in this query who as an infant showed only four tooth buds in the roentgenogram of the jaws and five years later has only four teeth, and in whom the absence of eyelashes is also noted, probably belongs to the group of cases collected under the title "hereditary ectodermal dysplasia." In the February 25 query it is noted that "x-ray examination of the skull shows unerupted teeth present. The film was not a good one." This information was rather indefinite, but by inference it was supposed that the tooth buds were present and that actual dentition was simply tardy. In the "hereditary ectodermal dysplasia" group there is frequently seen, along with the lack of development of most all of the teeth, other ectodermal defects, particularly of the skin, hair and nails, and there may even be absence of sweat glands. The absence of the eyelashes as noted in this query would make one suspect that this case belonged in that group. Kerley has recently reported such a case in which there was complete absence of all teeth. Several references related to this group are here listed:

Weech, A. A.: Hereditary Ectodermal Dysplasia, *Am. J. Dis. Child.* **37**: 766 (April) 1929.
Kerley, C. G.: Hereditary Ectodermal Dysplasia, *Arch. Pediat.* **55**: 211 (April) 1938.
Stein, J. L., and Gerber, Alexander: Congenital Absence of Teeth, *J. Pediat.* **13**: 547 (Oct.) 1938.

DISINFECTION OF THE SKIN

To the Editor:—Is it safe, after thorough scrubbing of the hands and arms and rinsing in sterile water, to immerse the hands and arms in compound solution of cresol? If so, what strength should be employed in preparation for an abdominal operation? The person in question is sensitized to both mercury bichloride and alcohol and seeks another safe means for preparation of the hands and arms.

M.D., Pa.

ANSWER.—Compound solution of cresol has strict limitations as a germicidal agent. With pure cultures of bacteria in vitro it may give good results but it cannot be relied on to disinfect the skin. On the skin it destroys "transient" bacteria readily but is much less effective against the "resident" bacteria. For discussion of these terms see the article by Philip B. Price (THE JOURNAL, Nov. 26, 1938, p. 1993).

Seventy per cent by weight alcohol is probably the most effective of available reagents for disinfecting the hands and arms. It is noted that in the inquiry the person in question is sensitive to alcohol. Most persons who regard themselves sensitive to alcohol base this opinion either on the use of 95 per cent alcohol or on the use of alcohol denatured by some irritating substance. It is suggested that the inquirer try 70 per cent by weight alcohol made with pure ethyl alcohol or alcohol denatured by the addition of boric acid only.

REFRIGERATOR GASES AND EYES

To the Editor:—Could you give me any information concerning antidotes used in the eyes against the various chemicals employed in electric refrigerators?

E. O. ALVIS, M.D., Indianapolis.

ANSWER.—Two chemical refrigerants, namely ammonia and sulfur dioxide, stand out as the chief sources of injury to the eyes. In addition to chemical action, actual freezing of a portion of the eye may result from a tiny jet of the chemical spurting into the eye. Ulceration may ensue in which chemical action may have a part. For the usual inflammatory injury to the eyes from ammonia, sulfur dioxide or conceivably the decomposition products of organic refrigerants, the immediate treatment is essentially the same. It is highly desirable that the injured eye be immediately and copiously laved with water. This may be followed by the introduction of saturated solution of boric acid. If pain is severe, the use of a local anesthetic such as 0.5 per cent solution of pontocaine hydrochloride is indicated. Thereafter, application of olive oil or some similar oil is desirable. Carbon dioxide is not known to produce injuries to the eyes except those resulting from freezing. A report by the Committee on Poisonous Gases was published in THE JOURNAL **94**:1832-1838 (June 7) 1930.

CHRONIC GONORRHEA AND SPERMATORRHEA

To the Editor:—A patient who had gonorrhea seven months ago seems cured so far as the urethra goes. In the last two months he has urinated a little too frequently in the daytime but rarely gets up nights to pass urine. There is a little burning. After having a stool he has developed the habit of pressing down as if to press more from the rectum but no stool passes; instead, a fluid passes from the urethra which looks a little like semen but shows no pus cells and few spermatozoa. I recognize nothing wrong in the prostate or in the seminal vesicles and analysis of the urine is negative. There are no strictures. I am wondering whether this is vesiculitis or a habit brought on by introspection. Can you suggest something that might help me clear the diagnosis—possibly a textbook.

M.D., Illinois.

ANSWER.—With the presence of frequency of urination and burning, it might be well to check the patient's prostate and seminal vesicles again by massage to make sure that the strippings are free of pus under the microscope. It is possible that the patient has a latent prostatitis or seminal vesiculitis—the remnants of the gonorrheal infection. Rectal examination is not sufficient in cases of this kind; therefore the prostate and vesicles should be stripped and the strippings examined. If the first examination is negative, two or three examinations should be made. If pus is found, the usual treatment such as massage, sitz baths and hot rectal irrigations is indicated. It might be

well to subject the patient to cystoscopy to rule out a lesion in the bladder, although this condition probably is remote.

It is possible that the patient has spermatorrhea. According to the statement made, he has developed the habit of "pressing down"; this pressure might act like massage and express the fluid from the seminal vesicles. The thing for the patient to do is to stop this habit of "pressing."

This subject is amply discussed in any of the standard textbooks on urology, such as those by Hinman, Keyes, Hermann, Hugh Cabot or Hugh Young.

SEROSANGUINEOUS DISCHARGE FROM UMBILICUS

To the Editor:—A girl aged 17 began last October having a serosanguineous discharge from the umbilicus four days after a regular menstrual period. The duration of the discharge is usually about fourteen days and it has occurred after every menstruation since the onset. The umbilicus has been examined repeatedly by myself and others, but no external opening can be found. The dressing has been sealed down over the umbilicus both with adhesive tape and with collodion, and always there is the same discharge on the dressing when it is changed. She states that on one occasion while this was going on she passed some blood in the urine. She was given methylene blue tablets and about forty-eight hours later a definite bluish tinge was found on the dressings on the umbilicus. She was roentgenographed after the bladder was filled with about 450 cc. of sodium iodide and the roentgenogram revealed a perfectly normal bladder without any connection with the umbilicus. Cystoscopic examination was also negative. No masses or swellings can ever be found about the umbilicus, and the pads, which are sometimes heavy with the discharge, do not have any odor. The patient has normal bleeding and clotting times and her blood picture is perfectly normal. In view of the fact that the bladder has been roentgenographed to rule out any connection with the umbilicus, that is, a patent urachus; that methylene blue stain was found on the pad after having been given by mouth; that there is no swelling around the umbilicus which would possibly signify an endometrial tumor; that there is no external opening for this discharge to come through, and since it has been sealed up to my satisfaction that the bloody discharge is not being put there from some other source, I would appreciate some help on this case. Am I dealing with some form of neurosis? Is it possible for this discharge to get through the skin without an external opening? Is methylene blue found in bloody discharges without any connection with the bladder? What else can I do to arrive at a diagnosis of this puzzling condition? Thank you for any help that you may be able to give me as to literature on similar conditions or as to suggestions on the best methods in handling this condition. W. C. MITCHELL, M.D., Smyrna, Ga.

ANSWER.—This is indeed a puzzling case. There appear to be two separate conditions. In spite of the absence of a palpable tumor at the umbilicus there is most likely an area of endometriosis on the peritoneal surface of the umbilicus or near it. Even though no opening is visible in the umbilicus, there is almost certainly a tiny opening present, if not at all times then only at the time when the serosanguineous discharge appears at the umbilicus. Otherwise it is impossible to explain a blood-tinged discharge after each menstrual period. Since no mention is made of any abdominal operation or any adhesion between the uterus and the abdominal wall, there is almost certainly no direct connection betwen the uterus and the umbilicus.

The presence of methylene blue at the umbilicus after the ingestion of this substance by mouth signifies that there is a connection betwen the urinary tract and the umbilicus. This may be a patent urachus.

The patient should have a complete study made of the urinary tract, including an intravenous pyelogram, and perhaps also instillation of methylene blue in the bladder to see whether any will appear at the umbilicus.

The entire case is puzzling, and the physician should make certain that the patient is not malingering. The greatest authority on the umbilicus is T. S. Cullen, whose monumental book "The Umbilicus" should be studied for additional information.

TISSUE CHEMISTRY AND AGE

To the Editor:—Osler has been quoted to the effect that aging is a process of increasing tissue acidosis. Is there any chemical proof of this? Have any comparative studies been made of the *p*H of tissue and blood, calcium phosphorus ratio, alkali reserve, and the like in childhood, youth, maturity and old age? B. A. FEDDE, M.D., Brooklyn.

ANSWER.—There is no good evidence that increased tissue acidosis goes hand in hand with increased age. Extensive comparative studies on tissues and blood at different ages do not appear to have been made. In general, with increased age there is a tendency to a lower content of water in nerve tissue and probably also in other tissues. The serum of adults contains higher concentrations of proteins than that of infants. The blood volume also increases per square meter of body surface area, with an increase up to adult age. However, the blood volume per kilogram of body weight decreases as adulthood is reached. None of these changes would lead to a decrease in alkali reserve.

LATE CLOSURE OF FONTANELS

To the Editor:—Will you kindly answer the following questions: 1. Is it true that the poet Dryden's fontanel did not close until he was 27 years old? 2. Are there other such examples of the late closing of the fontanel? 3. Does it indicate anything other than a probable case of rickets? 4. Could late closure of the fontanel be associated with some other condition—congenital syphilis, for example—which would impair mentality or distort personality? 5. What would be the present day treatment for such a condition? 6. Is there any one who makes a hobby of seventeenth century medicine?

CLARENCE W. LIEB, M.D., Tucson, Ariz.

ANSWER.—1. After considerable search in various libraries no information could be obtained as to the failure of the poet Dryden's fontanel to close until he was 27 years old. 2. In a cretin the fontanel may remain open beyond the usual time of closing, which is eighteen months; however, failure of closing of the fontanel after the twenty-fifth year must be an extremely rare condition. 3. Rickets delays ossification of normally formed cartilage. In severe renal rickets the fontanel does not remain open for any considerable length of time beyond that of normal closure. 4. Congenital syphilis is not usually associated with the late closing of the fontanel; this could, however, impair mentality or distort personality, as there are well authenticated cases of juvenile dementia praecox reported. 5. Present day treatment would depend on correct diagnosis. 6. There are probably some men who have made a hobby of seventeenth century medicine.

ASTHMA AND HERNIOTOMY

To the Editor:—A patient with chronic asthma (chronic allergic bronchitis) has developed an indirect inguinal hernia. Can you give me data on herniorrhaphy in asthmatic patients with regard to mortality and end results? WALTER I. WERNER, M.D., Albuquerque, N. M.

ANSWER.—There are two factors to be considered in reply to this query. One is the effect of a hernia operation on the asthmatic state and the other is the effect of the asthma on the herniotomy. In the majority of patients with asthma the asthmatic condition adds but little hazard to the surgical operation. There is a possibility, of course, of pulmonary complications, particularly massive pulmonary atelectasis. This can be minimized by the avoidance of preoperative and postoperative use of morphine and by hyperventilation of the lungs immediately after the operation. Local anesthesia also diminishes that possibility. On the other hand, operative procedures frequently have a beneficial effect on the asthmatic state for a period varying from a few weeks to a few months. The asthma itself with the chronic cough, of course, will add some increased possibility of a recurrence of the hernia. No statistical data with special reference to end results and mortality rate of herniorrhaphy in asthmatic individuals have been found.

SMALLPOX VACCINATION TECHNIC

To the Editor:—One of our best medicos here, who enjoys being different, is advising his patients to return six or seven days after being vaccinated to have the "blister" picked and dressed. It looks surgically sound to me. I would appreciate a discussion of this question in Queries and Minor Notes. M.D., Texas.

ANSWER.—The practice of treating the vesicle formed after vaccination for smallpox by surgical manipulation and dressing is not recommended by the various authors contributing authoritative essays on the subject. This procedure is not included in the manual of the United States Public Health Service under the description given for the technic and directions for vaccination against smallpox.

PETIT MAL

To the Editor:—In your issue of April 29, page 1752, there is a letter on petit mal I would like to express my disagreement with the statement that "petit mal epilepsy does not respond to any drug treatment." I have seen a number of patients who were much benefited by phenobarbital and recently I have seen very gratifying results from the use of diphenylhydantoin. In some cases in which neither drug worked alone, the use of three small doses of diphenylhydantoin during the day and one dose of phenobarbital at night had a conspicuously beneficial effect. I agree that in children the ketogenic diet is often better than drugs.

The term "pyknolepsy" is in my opinion overrated as an entity. I do not believe that it is anything more than a subvariety of epilepsy. One cannot divide these clinical types of seizures into anything like as simple a classification as grand mal, petit mal, pyknolepsy and equivalents. There are all sorts of intergradations between these four, and the arbitrary division obscures the biologic significance of the interrelationships.

Incidentally, there has recently been a tendency to use the term "petit mal epilepsy." I might point out that petit mal is always epilepsy, so the latter word is redundant. STANLEY COBB, M.D., Boston.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, June 17, page 2557.

STATE AND TERRITORIAL BOARDS

ARIZONA: Phoenix, July 5-6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

CALIFORNIA: *Written examinations.* San Francisco, July 10-13, Los Angeles, Aug. 7-10, and Sacramento, Oct. 16-19. *Oral examinations* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), Los Angeles, August 7, and San Francisco, Nov. 15. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO. Denver, July 10-12. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: *Medical (Regular).* Hartford, July 11-12. *Endorsement.* Hartford, July 25. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Medical (Homeopathic).* Derby, July 11-12. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: Dover, July 11-13. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: *Basic Science.* Washington, June 26-27. *Medical.* Washington, July 10-11. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

HAWAII: Honolulu, July 10-13. Sec., Dr. James A. Morgan, 48 Young Bldg., Honolulu.

IDAHO: Boise, Oct. 3-4. Dir., Bureau of Occupational License, Mr. H. B. Whittlesey, State Capitol Bldg., Boise.

ILLINOIS: Chicago, Oct. 17-19. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

IOWA: *Basic Science.* Des Moines, July 11. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, State Department of Health, Capitol Bldg., Des Moines.

MAINE: Augusta, July 11-12. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MASSACHUSETTS: Boston, July 11-13. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MONTANA: *Reciprocity.* Helena, Oct. 2. *Examination.* Helena, Oct. 3-4. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEBRASKA: *Basic Science.* Lincoln, Oct. 3-4. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

NEVADA: *Reciprocity and oral examination.* Carson City, August 7. Sec., Dr. John E. Worden, 311 W. Robinson St., Carson City.

NEW HAMPSHIRE: Concord, Sept. 14-15. Sec., Board of Registration in Medicine, Dr. T. P. Burroughs, State House, Concord.

NEW MEXICO: Santa Fe, Oct. 9-10. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York, and Syracuse, June 26-29. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Building, State Education Department, Albany.

NORTH DAKOTA: Grand Forks, July 5-8. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: Oklahoma City, Dec. 13. Sec., Dr. James D. Osborn, Jr., Frederick.

OREGON: *Basic Science.* Corvallis, July 8, and Portland, Oct. 28. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: *Written.* Philadelphia and Pittsburgh, beginning July 5. *Bedside.* Philadelphia, July 7-8. Dir., Bureau of Professional Licensing, Dr. James A. Newpher, 358 Education Bldg., Harrisburg.

PUERTO RICO: Santurce, Sept. 5. Sec., Dr. O. Costa Mandry, Box 3854, Santurce.

RHODE ISLAND: Providence, July 6-7. Sec., Dr. Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 27. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Rapid City, July 18-19. Director, Medical Licensure, Dr. G. J. Van Heuvelen, State Board of Health, Pierre.

UTAH: Salt Lake City, June 26-28. Dir., Department of Registration, Mr. G. V. Billings, 326 State Capitol Bldg., Salt Lake City.

WEST VIRGINIA: Bluefield, July 5. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: Milwaukee, June 27-30. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

Illinois April Examinations

Mr. Homer J. Byrd, superintendent of registration, Illinois Department of Registration and Education, reports the written examination (graduates of foreign schools given also a practical test) held in Chicago, April 11-13, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Thirty-nine candidates were examined, thirty-four of whom passed and five failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Northwestern University Medical School		(1938)	78, 87,* (1939) 80, 82, 82, 83, 83, 84, 85, 87
Rush Medical College		(1937)	80, 84, (1938) 83, 85
University of Illinois College of Medicine		(1937)	81, 85, (1938) 83
Harvard Medical School		(1932)	80
University of Minnesota Medical School		(1937)	83
Jefferson Medical College of Philadelphia		(1937)	86
University of Pennsylvania School of Medicine		(1937)	84
Marquette University School of Medicine		(1936)	79
University of Toronto Faculty of Medicine		(1928) (1936)	82, 89
University of Western Ontario Medical School		(1937)	84
Medizinische Fakultät der Universität Wien		(1923)	78
Friedrich-Wilhelms-Universität Berlin		(1922)	75
Ludwig-Maximilians-Universität Medizinische Fakultät, München		(1924) (1936)	78, 81
Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn.		(1938)	81
Regia Università degli Studi di Roma. Facoltà di Medicina e Chirurgia		(1933)	76
Universität Bern Medizinische Fakultät		(1937)	76,* 82

School	FAILED	Year Grad.
Medizinische Fakultät der Universität Wien		(1936)
Univerzita Komenského Fakulta Lekárska, Bratislava		(1934)
[illegible] Medizinische Fakultät, Freiburg		(1922)
[illegible] Fakultät		(1922)
[illegible] Roma. Facoltà di Medicina e Chirurgia		(1937)

Eighteen physicians were successful in the practical examination for reciprocity and endorsement applicants held in Chicago, April 13. The following schools were represented:

School	PASSED	Year Grad.	Reciprocity with
Rush Medical College		(1937)	Louisiana
Indiana University School of Medicine		(1933)*	Indiana
State University of Iowa College of Medicine		(1931)	Iowa
University of Kansas School of Medicine		(1927)*	Kansas
Harvard Medical School		(1934)	Penna.
Wayne University College of Medicine		(1935)	Michigan
University of Minnesota Medical School		(1934), (1937)	Minnesota
St. Louis University School of Medicine		(1933), (1936)	Missouri
Washington University School of Medicine		(1932)	Missouri
Western Reserve University School of Medicine		(1937)	Ohio
Meharry Medical College		(1937)	Tennessee
University of Tennessee College of Medicine		(1937)	Tennessee

School	PASSED	Year Grad.	Endorsement of
College of Medical Evangelists		(1935)	N. B. M. Ex.
Northwestern University Medical School		(1938)	N. B. M. Ex.
Rush Medical College		(1937)	N. B. M. Ex.
Medical College of the State of South Carolina		(1936)*	N.B.M.Ex.

*License has not been issued.

Maine March Examination

Dr. Adam P. Leighton, secretary, State of Maine Board of Registration of Medicine, reports the written examination held at Portland, March 14-15, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Twelve candidates were examined, ten of whom passed and two failed. Two physicians were licensed by reciprocity and one physician was licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Boston University School of Medicine		(1937)	81
Harvard Medical School		(1936)	82
Tufts College Medical School		(1922) (1938)	79, 78
University of Michigan Medical School		(1937)	83
University of Minnesota Medical School		(1937)	85
University of Rochester School of Medicine		(1937)	82
Hahnemann Medical College and Hospital of Philadelphia		(1938)	81
Regia Università degli Studi di Roma. Facoltà di Medicina e Chirurgia		(1935)	78
Universität Basel Medizinische Fakultät		(1937)	81

School	FAILED	Year Grad.	Per Cent
Georg August-Universität Medizinische Fakultät, Göttingen		(1919)	74
National University of Athens School of Medicine		(1935)	53

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Tufts College Medical School		(1936)	New Hamp.
Regia Università degli Studi di Roma. Facoltà di Medicina e Chirurgia		(1936)	Maryland

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
University of Pennsylvania School of Medicine		(1934)	N. B. M. Ex.

Missouri Reciprocity and Endorsement Report

Dr. Harry F. Parker, secretary, State Board of Health of Missouri, reports seven physicians licensed by reciprocity and one physician licensed by endorsement at the meeting held in Excelsior Springs, April 10, 1939. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas School of Medicine		(1930), (1937)	Arkansas
Rush Medical College		(1934)	W. Virginia
Tulane University of Louisiana School of Medicine		(1937)	Louisiana
University of Tennessee College of Medicine		(1936), (1937), (1938)	Tennessee

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
St. Louis University School of Medicine		(1935)	N. B. M. Ex.

Book Notices

English, German, French, Italian, Spanish Medical Vocabulary and Phrases. By Joseph S. F. Marie. Foreword by Chevalier Jackson, M.D., Sc.D., LL.D., Honorary Professor of Broncho-Esophagology and Consultant in Broncho-Esophagologic Research, Temple University School of Medicine, Philadelphia. Cloth. Price, $3. Pp. 358. Philadelphia: P. Blakiston's Son & Co., Inc., 1939.

Here is the kind of book that has been wanted by many physicians, namely an English, German, French, Italian and Spanish medical vocabulary with useful phrases. Dr. Chevalier Jackson says that it makes him sad to think of the thousands of weary hours that he might have saved had he had a book of this type available. In alphabetical form the book lists some thousands of terms in English with German, French, Italian and Spanish equivalents. At the end, as supplements, there are sections on pronunciation and also a series of phrases such as might be needed by the physician in making an examination or in giving directions.

Valutazione biologica dei medicamenti. Dal Dott. Prof. Giulio Buccardi del *Laboratorio Farmacologico Dr. Recordati, Correggio.* Cloth. Price, 120 lire. Pp. 561, with 70 illustrations. Florence: G. C. Sansoni, 1938.

It is perfectly correct, as stated by Dr. Recordati in his introducation to this book, that "We need not only in Italy but elsewhere a manual which contains practical descriptions in detail of the methods for the bio-assay of medicinal preparations." This is especially true of a book on the subject so thoroughly abreast of the times as this one. It is most interesting to note that the bio-assay of drugs, which until recent years was the chief concern of books on this subject, occupies merely one fourth of this book. The rest is taken up with the bio-assay of hormones, vitamins and antiserums. Very valuable also is the "general part," which includes a discussion of equipment for bio-assay, general directions for it, and a brief exposition of statistical methods as applied to it. Our Italian confrères are to be congratulated on the possession of this book, the acquisition of which can be unreservedly recommended to bio-assay laboratories in other parts of the world, even if they need to engage a translator.

Report of the Medical Research Council for the Year 1937-1938. Presented by the Lord President of the Council to Parliament by Command of His Majesty February 1939. Paper. Price, $1.05. Pp. 221. New York: British Library of Information; London: His Majesty's Stationery Office, 1939.

It is impossible to do justice in the space available to the extensive field of investigation covered by this report. Actual promotion of specific research by the Medical Research Council is usually done by appointment of individuals to the permanent staff. Such appointments depend on the subject which seems to require special attention and on the merits of the persons chosen. When once appointed, an individual has wide liberty of action in planning investigation. The council seldom chooses particular diseases for investigation but it designed to include the study of etiologic factors common to a group of diseases, a type of treatment of wide application or a system of physiologic or biochemical control. Examples now under investigation are virus diseases, endocrinology and chemotherapy. Another part of the work of the council consists of personal and expense grants, the initiative in choice of subject and method of investigation lying with the head of a laboratory or hospital or with the worker himself. An important duty of the Medical Research Council since its beginning has been to help government departments confronted with immediate problems of health and disease. The National Institute for Medical Research has a large staff at work on important investigations related to virus diseases, transmissible tumors, lung cancer and dust, chemotherapy, endocrinology and other broad problems. The Institute for Medical Research also carries out extensive work on the standardization of biologic products in a manner in some respects similar to that of the U. S. Bureau of Standards. There are a number of clinical research units staffed and supported by the council in several recognized institutions. All these have been producing important investigation for a considerable period and include such well known units as the Clinical Research Unit, Guy's Hospital and the Department of Clinical Research at the University College Hospital, London, under the direction of Sir Thomas Lewis. The council has also made an important contribution by grants-in-aid for medical research and is active in research in tropical medicine and in industrial health. In all, the report reflects many of the advantages of centralized direction without dictation of actual research problems. It may be recommended to the careful perusal of all those interested in the advance of scientific medicine.

Thus We Are Men. By Sir Walter Langdon-Brown, M.A., M.D., LL.D., Consulting Physician to St. Bartholomew's Hospital, London. Cloth. Price, $3.50. Pp. 344. New York: Longmans, Green & Co., 1939.

Among the most erudite and clever of British writers in the field of medicine today is Sir Walter Langdon-Brown, emeritus professor of physic and fellow of the Corpus Christi College in the University of Cambridge. This series of lectures comprises such important addresses as the Maudsley, the Cavendish and the Sir Charles Hastings memorial lecture. There are also the contributions to the Harveian Society, the Abernethian Society and the Osler Club. Every one of the essays is thought provoking and mentally stimulating. There are many quotable paragraphs. For example, "In disease of the body the higher levels which develop last suffer first, for they have not had time to acquire such a firm hold on the instincts of the organism as the lower. In the same way the body politic evolves its higher levels later than the individuals composing it. A committee is always more ready to perpetrate an injustice than its individual members would be."

The first lecture, on "The Biology of Social Life," reveals a penetrating analysis of present international relationships from the biologist's point of view. In the essay entitled "The Return to Aesculapius" there are some profound thoughts on the basis for quackery. Here are some interesting concepts regarding Christian science and osteopathy. The author's reading has been wide and he seems familiar with the important notes from here and there throughout the world.

The biographic essays which concern Osler and Robert Bridges are inspiring, and there is a chapter on "The Psychology of Authorship" which reveals an erudition far beyond that of most physicians. Unusual is the essay on "The Evolution of Death," and the final essay, "Retrospect," ends with the following philosophy: "It is sometimes well to realize, as life goes on, that we must leave things to younger men to accomplish. We may see a new truth but be too set in our ways to ensue it. It is well to be able to say 'The life to which I belong uses me and will pass beyond me, and I am content.'"

The Evolution of Obstetric Analgesia. By Andrew M. Claye, M.D., F.R.C.S., F.C.O.G., Professor of Obstetrics and Gynaecology, University of Leeds. With a chapter by W. Stanley Sykes, M.A., M.B., B.Ch., Honorary Anaesthetist, General Infirmary at Leeds. Cloth. Price, $2. Pp. 103, with 5 illustrations. New York, Toronto & London: Oxford University Press, 1939.

The author wrote this book because "no English volume solely on the subject has stressed its historical aspect." He discusses the two main landmarks, the introduction of ether and chloroform into obstetrics by Simpson and the elaboration of twilight sleep by Gauss. Likewise he expresses his own ideas concerning the scopolamine-morphine technic, which he learned from Gauss in Würzburg in 1931. There are also chapters on scopolamine amnesia, the barbiturates and more inhalation anesthetics, nitrous oxide and ethylene, the last written by W. Stanley Sykes. Claye says "We have on my suggestion aimed at giving some form of analgesia to every patient in labor. . . . This, as regards inhalation anesthetics, is carried out almost entirely by medical students and . . . the work has been in the great majority of cases conscientiously and efficiently done." In the United States, medical students are rarely permitted to give inhalation anesthetics. Claye further remarks "I think . . . it is much safer for the doctor to give the anesthetic, which he should be competent to do, and for the nurse to take the delivery, which she should be competent to do. The reverse process is not uncommon." Of course the author refers to nurses who have had good training in obstetrics and who are nurse midwives. In this country inhalation anesthetics are nearly always administered by doctors or nurses who are especially trained in inducing anesthesia. This small book contains nothing new.

Apparently the author regards Gauss as of equal importance with Simpson in the field of obstetric analgesia and anesthesia (he uses these terms interchangeably). He includes photographs of both men. The chapter on twilight sleep, which contains Gauss's name innumerable times, is longer than the chapter devoted to Simpson.

Out of the Running. By G. Gertrude Hoopes. With a foreword by Edgar A. Doll, Ph.D., Director of the Department of Research, The Training School at Vineland, New Jersey, and with clinical notes by Winthrop M. Phelps, M.D., Director of the Children's Rehabilitation Institute, Inc., Baltimore. Cloth. Price, $2. Pp. 158, with 4 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1939.

Gertrude Hoopes is in many ways far from being "out of the running," though she is severely handicapped by infantile cerebral palsy. Practically unable to walk, she gets about on a specially constructed tricycle; unable to talk, she has evolved a shorthand sign language and joins conversations by pointing to letters of the alphabet. Despite her handicaps, she has lived a very active life and has enjoyed the friendship of many cultured and prominent persons. Throughout the book one is continually reminded that through her religious faith she was able to conquer feelings of depression and morbidity which would assail her when she contemplated how different her life was from that of the normal person. So strong were these feelings that on two occasions she attempted suicide, but so strong has her belief in religion become that never since has the thought of suicide troubled her. Infantile cerebral palsy is the most neglected of all crippling conditions, and the goal in working with handicapped persons is to educate and train them so that they may return to society and find a place in life. It evidently has not been necessary for Miss Hoopes to earn her own living, but if it were she could probably develop her writing ability to the extent of becoming financially independent. It is regrettable that Miss Hoopes has not included a purely objective chapter in her book. It is partially the objective treatment of Helen Keller's life that makes her biography remarkable, since it shows definitely how the blind and deaf may overcome their handicaps and become useful citizens. When medicine and surgery fail to aid the blind and the deaf, special education steps in to help them cross the physical barriers. Neither surgery nor medicine has contributed a great deal to Miss Hoopes's happiness. Her physical barriers have been crossed by her determination and refusal to become discouraged and by her ingenious devices, such as the tricycle and her clever method of carrying on a conversation. Her story therefore should arouse a greater interest in promoting special education in cases of infantile cerebral palsy.

The Chemistry of the Carbon Compounds. By Victor von Richter. Edited by the late Prof. Richard Anschütz. Volume II: The Alicyclic Compounds and Natural Products. Translated from the XIIth German edition and revised by T. W. J. Taylor, M.A., Fellow and Tutor of Brasenose College, Oxford, and A. F. Millidge, Ph.D., B.Sc. Third edition. Cloth. Price, $15. Pp. 656. New York: Nordemann Publishing Company, Inc.; Amsterdam: "Elsevier," 1939.

This volume will be welcomed not only by the investigator in chemistry but also by many others, particularly as a source of information on chemistry. It is a companion to volume I and, like it, needs no introduction to the chemist. The scope of the volume is broad, correlating an enormous amount of organic material, including the alicyclic series and natural products, such as glucosides, natural coloring substances, vitamins and hormones.

Registro e interpretación de la actividad cardíaca. Por Oscar Orías, professor de fisiología y director del Instituto de fisiología de la Facultad de ciencias médicas de Córdoba (República Argentina). Third edition. Paper. Pp. 199, with 81 illustrations. Buenos Aires: Librería y editorial "El Ateneo," 1939.

This excellent short, beautifully illustrated monograph on the graphic methods of recording the heartbeat has had a deserved popularity, as evidenced by a third edition in a few years. The material is based in part on the work of Wiggers and his school, which includes the author, and in part on the further work which the author did on his return to South America. The material is presented in its application to clinical conditions. It is encouraging to know that such fundamental work is being disseminated among the Spanish speaking members of the medical profession.

Clinical Bacteriology. By F. A. Knott, M.D., M.R.C.P., D.P.H., Director, Bacteriological Department, Guy's Hospital. Cloth. Price, $4.50. Pp. 426, with 60 illustrations, including 12 plates. Philadelphia: P. Blakiston's Son & Co., Inc., 1939.

This small book was written for the purpose of impressing the reader with the clinical significance of bacteriologic phenomena. There are no references to the literature in the text, and the public health aspects represent the practices in Great Britain rather than those in this country. There are many inaccuracies in the book. For example, in the discussion on tularemia the author states that "the disease has so far been met with only in America." Tularemia was reported in Japan in 1925, Russia in 1928, Norway in 1929, Sweden in 1931 and Austria in 1935. The last chapter deals with normal flora of the body. An appendix includes material on bacteriologic culturing, staining and serologic methods and the preparation of bacterial vaccines and two pages on fungous infections. The illustrations and plates are excellent. This book can be recommended for the physician's library but is inadequate for the medical student.

Die Arzneikombinationen. Von Professor Dr. Emil Bürgi. Paper. Price, 12 marks. Pp. 169, with 28 illustrations. Berlin: Julius Springer, 1938.

The author quotes an ancient Babylonian inscription, "To give a medicine the desired quality, it must be combined of at least two active substances that through suitable quantitative relations antagonize each other's harmful effects while they mutually increase their desired action." It remained for Bürgi, the author of this book, to codify this 4,000 year old proposition and to publish it in 1909 in the form of his well known "law" or, better, rule, which may be formulated thus: Substances that have the same final effect have, when combined, additive action if they have the same point of attack and a superadditive effect when they have a different pharmacologic mode of action. This rule is true not only of drugs but also of nonmedicinal measures and of combinations of these two, e. g. mountain climate and iron in the treatment of anemia. In the present book the author discusses under the various therapeutic headings the facts and the literature that have accumulated proving the validity of his "law." To all who are interested in efficient therapy this book can be highly recommended. It is indispensable for teachers of pharmacology and therapeutics.

***Olla Podrida*: Piquant Spanish Dishes from the Old Clay Pot.** By Elinor Burt. Cloth. Price, $3. Pp. 277. Caldwell, Idaho: Caxton Printers, Ltd., 1938.

With many Americans, enjoyment of Spanish cooking is more of a novelty than a fad. The author of this volume has had cooperation from many leading experts in the development of the book, including Spanish students, and has had also a year of work in the Bureau of Home Economics in Washington, D. C. The book contains not only brief essays discussing the nature of the special cooking of Spanish, Mexican, Creole and Latin-American types but also a number of interesting recipes.

Chemical Analysis for Medical Students: Qualitative and Volumetric. By R. E. Illingworth, Ph.D., B.Sc., Lecturer in Chemistry, School of Medicine of the Royal College, Edinburgh. With a foreword by G. Barger, ScD., LL.D., F.R.S., Regius Professor of Chemistry, University of Glasgow, Glasgow. Cloth. Price, $1.50. Pp. 152, with one illustration. Baltimore: William Wood & Company, 1938.

For this textbook, primarily intended for first year medical students, the subject matter was selected at Edinburgh medical schools with the hope that it might be of value in other similar institutions. The volume will be of value to those interested in qualitative analysis and will prove useful.

Personality Development and Social Control in Terms of Constitution and Culture. By Ira S. Wile, M.S., M.D. Three Lectures at The Tavistock Clinic, July 1937. Paper. Price, $1.25. Pp. 57. New York & London: Oxford University Press, 1939.

This is a collection of three lectures given by the author at the Tavistock Clinic in July 1937 entitled "Personality in Terms of Constitution," "Personality in Relation to Culture" and "Social Control and the Prevention of Personality Disorders." As might be expected, they reflect the broad culture and philosophical and medical background of the author.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Accident Insurance: Scarlet Blotch on Skin as "Visible Contusion or Wound."—The defendant issued an insurance policy providing double indemnity if "the death of the insured occurred . . . as a result, directly and independently of all other causes, of bodily injuries, effected solely through external, violent and accidental means, of which, except in case of drowning or of internal injuries revealed by an autopsy, there is a visible contusion or wound on the exterior of the body." The insured was found dead on the floor of a garage about 2 feet from the exhaust pipe of an automobile. There were scarlet blotches on his face, trunk and extremities, indicative that death was due to carbon monoxide poisoning. From a judgment allowing recovery under the policy, the defendant insurance company appealed to the United States circuit court of appeals, seventh circuit.

The insurance company denied liability, contending that the scarlet blotches were not a "contusion or wound" within the meaning of the policy. It is true, answered the court, that, etymologically, "contusion" suggests an injury which is the result of the impact of a blow on the exterior of the body. The purpose of the policy, however, in conditioning liability on the presence of a "visible contusion or wound on the exterior of the body" was to have visible, physical evidence of the operation of the "external, violent and accidental means," which are alleged to have effected the bodily injuries. "Visible contusion," as used in the policy, included, the court thought, any morbid change in or injury to either the subcutaneous tissue or the skin which produces markings or discolorations visible on the exterior of the body. It is not material whether the "visible contusion" results directly from the operation of the "means" on the exterior of the body or indirectly from the internal injuries which are effected by the action of the "means." The accidental operation of external means may be wholly internal, and yet the internal injuries may extend to the subcutaneous tissue or into the layers of the skin. The visibility of the "contusion" may be due to the discoloration either of the injured tissue under the skin or of the injured skin itself, or of both. The scarlet blotches on the exterior of the body of the insured were caused by the action of the carbon monoxide and were connected with the "internal injuries" which resulted in the death of the insured. When carbon monoxide is inhaled into the lungs it passes into the blood and combines with the hemoglobin contained in the red blood cells. As a result, tissue cells are deprived of an adequate supply of oxygen. This, in turn, causes the death and decomposition of tissue cells, which results in the appearance of scarlet blotches on the exterior of the body. The court held, therefore, that the scarlet blotches were visible contusions or wounds within the meaning of the policy and the judgment against the insurance company was affirmed.—*Warbende v. Prudential Ins. Co. of America, 97 F. (2d) 749.*

Accident Insurance: Amebic Dysentery Not a Bodily Injury Sustained Through Accidental Means.—The defendant insurance company insured Burns "against bodily injuries sustained . . . solely and independently of all other causes through accidental means." A sewer pipe broke in a hotel in which Burns was registered and contaminated the drinking water with amebae. Burns contracted amebic dysentery as a result of drinking the water and eventually died. In a suit which Burns' beneficiary subsequently instituted on the policy the trial court entered a judgment for the insurance company on the pleadings. The beneficiary appealed to the court of appeals of Ohio, which reversed the cause and remanded it to the trial court, but a motion to certify the record to the Supreme Court of Ohio was allowed.

The question to be determined, said the Supreme Court, is whether a death from amebic dysentery contracted from drinking contaminated water is the result of a bodily injury sustained by accidental means. Generally an accident is considered as an event proceeding from an unexpected happening or unknown cause without design and not in the usual course of things. The court found no difficulty in holding that Burns' death was due to amebic dysentery which was accidentally contracted. The amebae contaminated the water by an accident, the breaking of the sewer pipe. It was likewise accidental that they entered Burns' system. A more difficult question was whether or not the contraction of amebic dysentery was a bodily injury. There was, said the court, no violence, vis major, or other casualty which operated directly on Burns. Many courts have held that deaths or disabilities resulting from the mechanical action of food or drink, ptomaine poisoning, alcoholic poisoning, infections of the eye by gonococci, blood poisoning, carbon monoxide poisoning, typhoid and from "drinking milk of cows which had eaten golden rod" were due to a bodily injury within the terms of insurance policies containing provisions somewhat similar to the policy involved in this case. The Supreme Court, however, was not impressed with these decisions. Those cases, said the court, proceeded on the theory that the policy under question must be construed most strongly against the insurer, whose duty it was to exclude specifically the risks if there was doubt. But a court should not resort to a construction never conceivably intended by the parties.

To uphold the theory of recovery in this case, continued the court, would be to hold that all diseases are bodily injuries. There would thus be no difference between an accident policy and a health policy, except insofar as it would be necessary, to recover on an accident policy, to trace the cause to some mischance. In the present case, the policy was not a general health policy but a limited accident policy, and the premium collected was for a limited coverage. Bodily injury should be considered as limited to bodily injuries resulting from physical or external forces known as accidents. Pneumonia, typhoid, scarlet fever and the like are diseases due solely to germs. To call them bodily injuries is to establish a new nomenclature and classification not generally used in ordinary conversation. The words "bodily injury" are commonly and ordinarily used to designate an injury caused by external violence, and they are not used to indicate disease. The court believed that the words "bodily injury" as used in this policy were used in their common and accepted meaning and that to create liability there must be evidence of some external or violent and accidental force or cause. No such evidence was present in this case. The court accordingly affirmed the judgment of the trial court directing a verdict in favor of the insurer.—*Burns v. Employers' Liability Assur. Corporation, Limited, of London, England (Ohio), 16 N. E. (2d) 316.*

COMING MEETINGS

American Association for Thoracic Surgery, Los Angeles, July 5-7. Dr. Richard H. Meade Jr., 2116 Pine St., Philadelphia, Secretary.

American Physiotherapy Association, Denver, June 25-30. Mrs. Eloise T. Landis, 2065 Adelbert Road, Cleveland, Secretary.

American Proctologic Society, Brooklyn, N. Y., June 25-27. Dr. Curtice Rosser, 710 Medical Arts Bldg., Dallas, Texas, Secretary.

Maine Medical Association, Poland Springs, June 25-27. Dr. F. R. Carter, 22 Arsenal St., Portland, Secretary.

Medical Library Association, Newark, N. J., June 27-29. Miss Janet Doe, 2 East 103d St., New York, Secretary.

Montana, Medical Association of, Butte, June 28-30. Dr. Thomas L. Hawkins, 50 North Main St., Helena, Secretary.

National Medical Association, New York, Aug. 15-19. Dr. John T. Givens, 1108 Church St., Norfolk, Va., General Secretary.

National Tuberculosis Association, Boston, June 26-29. Dr. Charles J. Hatfield, 50 West 50th Street, New York, Secretary.

Pacific Coast Oto-Ophthalmological Society, San Francisco, June 19 22. Dr. C. Allen Dickey, 450 Sutter St., San Francisco, Secretary.

West Virginia State Medical Association, White Sulphur Springs, July 10-12. Mr. Joe W. Savage, Public Library Bldg., Charleston, Executive Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Coronary Sclerosis: Analysis of 928 Cases. B. J. Clawson, Minneapolis.—p. 387.
Blood Oxygen Changes Following Intermittent Venous Occlusion. J. R. Veal, Washington, D. C., and W. M. McCord, New Orleans.—p. 401.
Normal Heart Volume in Man. G. Liljestrand, E. Lysholm, G. Nylin and C. G. Zachrisson, Stockholm, Sweden.—p. 406.
Follow-Up Study of Systolic Murmurs. M. J. Shapiro, Minneapolis.—p. 416.
Transient Bundle Branch Block and Other Electrocardiographic Changes in Pulmonary Embolism. T. M. Durant, I. W. Ginsburg and H. Roesler, Philadelphia.—p. 423.
Tumors of Heart and Pericardium. R. W. Scott and C. F. Garvin, Cleveland.—p. 431.
Premature Closure of Foramen Ovale: Report of Two Cases. Miriam Crowell Benner, Denver.—p. 437.
Coarctation of Aorta, Nonclinical Type, Associated with Congenitally Bicuspid Aortic Valve: Method for Its Recognition, with Report of Case. P. Hallock and R. Hebbel, Minneapolis.—p. 444.
*Nonrheumatic Calcific Aortic Stenosis. C. K. Friedberg and A. R. Sohval, New York.—p. 452.
Development of Electrocardiogram of Embryonic Heart. E. C. Hoff, New Haven, Conn.; T. C. Kramer, Ann Arbor, Mich.; D. DuBois, New Haven, Conn., and B. M. Patten, Ann Arbor, Mich.—p. 470.

Nonrheumatic Calcific Aortic Stenosis.—Friedberg and Sohval review the clinical features of fifteen necropsy cases of calcific aortic stenosis in which the possibility of a rheumatic etiology had been previously excluded. As a corollary they attempted to determine whether it was clinically possible to differentiate the rheumatic from the nonrheumatic cases. The differentiation of calcific aortic stenosis from coronary artery disease may be extremely difficult because the symptoms of both are due essentially to myocardial ischemia. Attacks of dizziness and syncope, when present, favor a diagnosis of calcific aortic stenosis rather than arteriosclerotic heart disease. If, in addition, there is a distinctive murmur or a systolic thrill, the differentiation from coronary artery disease is clear. Calcific aortic stenosis should be considered as a diagnostic possibility in any patient with cardiac failure of obscure etiology. The differentiation of rheumatic from nonrheumatic calcific aortic stenosis usually cannot be made from the symptoms and physical signs alone. If the patient is less than 50 years of age, the aortic stenosis is usually due to rheumatic fever. When the physical signs of mitral stenosis are uncertain, x-ray evidence of unusual left auricular or right ventricular enlargement suggests associated rheumatic mitral disease. Similarly, if the electrocardiogram shows right ventricular preponderance, due apparently to mitral disease, the calcific aortic stenosis is probably rheumatic.

American Journal of Cancer, New York

35: 491-656 (April) 1939

Morphologic Resemblance of Pulmonary Adenomatosis (Jaagsiekte) in Sheep and Certain Cases of Cancer of Lung in Man. C. Bonne, Batavia, Java, Netherlands Indies.—p. 491.
Effect of Freezing in Vitro on Some Transplantable Mammalian Tumors and on Normal Rat Skin. G. B. Mider and J. J. Morton, Rochester, N. Y.—p. 502.
Contributions to Tissue Culture Technic. J. P. M. Vogelaar and Eleanor Erlichman, New York.—p. 510.
Primary Liver Cell Carcinoma with Splenic Metastases. A. F. Liber and C. R. Brown, New York.—p. 521.
Reticulum Cell Sarcoma of Spleen. M. Gerundo and M. B. Miller, Topeka, Kan.—p. 528.
Carcinoma of Kidney in Rats Treated with Beta-Anthraquinoline. A. Sempronj and E. Morelli.—p. 534.
Production of Lung Tumors in Mice by Intratracheal Administration of Carcinogenic Hydrocarbons. M. B. Shimkin, Cambridge, Mass.—p. 538.
Effect of 1,2,5,6-Dibenzanthracene on Growth and Respiration of Yeast. E. S. Cook Sr., Mary Jane Hart and R. A. Joly, Cincinnati.—p. 543.
Vitamin E and Experimental Tumors. C. Carruthers, Iowa City.—p. 546.
*Statistical Relation Between Goiter and Cancer. J. F. McClendon, Minneapolis.—p. 554.

Goiter and Cancer.—McClendon discusses the possibility of some causal relation between goiter and cancer. It seems possible that a single thyroid cell might break loose and traveling in the blood stream either disintegrate, or, finding a favorable environment in the wall of the alimentary tract, undergo a metamorphosis and become the starting point of a supposedly primary cancer of the alimentary tract. Another possible causal relationship between goiter and cancer is that the thyroid hormone causes differentiation of cells. Deficiency of this hormone might permit some cells to remain undifferentiated and therefore potentially precancerous. The author presents statistics and states that, although they may not be regarded as entirely sufficient to establish a relation between goiter and cancer, the evidence is quite conclusive that thyroid adenoma may predispose to cancer of the thyroid and is an ample warning that goiter may constitute a danger of increasing the cancer rate. Therefore goiter prophylaxis with iodine in the young and desiccated thyroid in the aged may be a precaution worth taking to prevent an increase in the incidence of cancer.

Annals of Internal Medicine, Lancaster, Pa.

12: 1555-1738 (April) 1939

Observations on Treatment of Lipoid Nephrosis. R. H. Major, Kansas City, Kan.—p. 1555.
Renal Threshold for Glucose; Clinical Observations on Case of Non-diabetic (Renal) Glycosuria. H. M. Thomas Jr. and H. Southworth, Baltimore.—p. 1560.
Importance to the Internist of Latent Paranasal Sinusitis. G. H. Lathrope, L. A. Peer and R. Paddock, Newark, N. J.—p. 1576.

*Tropical and Nontropical Sprue (Chronic Idiopathic Steatorrhea): Their Probable Interrelationship. A. M. Snell, Rochester, Minn.—p. 1632.
Gold Therapy in Arthritis: Observations on 100 Cases Treated with Gold Sodium Thiosulfate and Aurocein. R. G. Snyder, C. Traeger and L. Kelly, New York.—p. 1672.
Rightward Deviation of Axis of the T Wave as Index of Myocardial Disease. R. Ashman and Eleanor H. Hidden, New Orleans.—p. 1682.

Tropical and Nontropical Sprue.—Snell reports thirty-two cases of "nontropical" sprue or "idiopathic steatorrhea" affecting residents of the Central and North Central states. Also fourteen cases of sprue contracted in the tropics are reviewed. The cases of nontropical sprue differ from tropical sprue chiefly by virtue of their extreme chronicity and an associated tendency to disturbed calcium metabolism and skeletal deformities. The common features of the thirty-two cases of nontropical sprue were glossitis and stomatitis, emaciation, fatty diarrhea, various types of anemia, disturbances of the metabolism of calcium and of protein, and a group of symptoms related to various vitamin deficiencies. There are no definite prodromal symptoms of nontropical sprue, although certain patients who later had the classic disease gave a history of chronic remittent gastrointestinal disturbances, nausea, vomiting, anorexia, intolerance to food and intestinal irritability. Physical examination revealed a most striking degree of malnutrition with muscular wasting and cachexia. Twenty patients presented symptoms and signs which were virtually identical with those seen in tropical sprue; in these patients there was a definite beneficial response to liver extract. The remaining twelve patients presented various metabolic and nutritional disturbances, including tetany, osteoporosis, hypoproteinemia and various vitamin deficiencies. The condition in these cases was identical in all respects to that described in the English and Scandinavian literature as "idiopathic steatorrhea." The response to liver extract in these cases was often unsatisfactory but, in certain cases in which the patients were adequately treated, good results were obtained. Since the sprue syndrome is not uncommon in temperate climates its earlier recognition and treatment would largely eliminate the late "complicated" cases.

Occurrence of Pick's Disease in Early Adult Years. K. Löwenberg, D. A. Boyd Jr. and D. D. Salon, Ann Arbor, Mich.—p. 1004.
Easily Made Apparatus for Use in "Closed System" Pneumo-Encephalography, with Notes on Technic for Its Use. W. L. Holt Jr. and R. S. Schwab, Boston.—p. 1021.

Remissions in Multiple Sclerosis.—Brown and Putnam present their observations in 133 cases of multiple sclerosis, ninety-five of which were observed in the wards of the neurologic unit and thirty-eight were seen in office practice. There was a striking difference between the course of the illness in the two groups. Periods of improvement were reported in thirty-three of the thirty-eight and in only fifty-nine of the ninety-five. In all, 550 separate symptoms were recorded in the 133 cases. The report covers 1,095 "patient years" of the disease. During the period under consideration, 239 instances of improvement were reported by ninety-two of the 133 patients. In the others the disease was uninterruptedly progressive or stationary after a single attack. Ambulatory patients seen in "office" practice were found to have a significantly longer and milder course with more remissions than those seen in "hospital" practice. In general, symptoms evidently due to small lesions, such as diplopia, central scotoma or sensory disturbances of one extremity, tend to regress within a few months. Symptoms apparently due to large lesions, such as paraplegia, ataxia and mental deterioration, are usually permanent. As a rule, isolated symptoms disappear in a far higher proportion of instances than do the same symptoms occurring in conjunction with others. Symptoms tend to grow more severe as the disease progresses. Most lesions of multiple sclerosis go through an acute stage, after which a variable number of fibers regain the ability to conduct impulses. Certainly in most large lesions, and probably in all lesions, there is permanent destruction of the conductivity of some or many fibers.

Sequelae of Postmeasles Encephalomyelitis.—Malamud reports two cases which illustrate the sequelae of postmeasles encephalomyelitis and he traces the manner in which this terminal condition develops from the preceding acute and subacute stages. Such an investigation, he states, may also be of value in differentiating disseminated encephalomyelitis from multiple and diffuse sclerosis, concerning which there is considerable confusion in the literature. The permanent sequelae of postmeasles encephalomyelitis were characterized in one case by predominantly hemiplegic manifestations and in the other case by hyperkinesis, personality change, mental enfeeblement and ataxia. Such symptoms, according to Ford, are frequent complications of this disorder. In the first case the development of the neurologic disturbance during the prodromal period of measles does not contradict the diagnosis. In the second case the hyperkinetic syndrome closely resembled the disturbances following epidemic encephalitis in childhood. The clinical course was not progressive; the symptoms remained stationary and in the first case they even partially receded. The lesions in the two cases were localized exclusively in the white matter and occurred in three predilective sites: (1) perivascularly (perivenously) within the white substance of the cerebrum and cerebellum, (2) subependymally in the vicinity of the ventricles and (3) marginally in the spinal cord. Histologically, the lesions were poorly outlined coalescing foci of demyelination, in which myelin sheaths and axis cylinders were equally destroyed. They were uniformly replaced by dense glial scars devoid of any signs of inflammation. Fundamental differences between disseminated encephalomyelitis and multiple and diffuse sclerosis are outlined.

Congenital Familial Ophthalmoplegia.—Helfand reports a case of congenital familial external ophthalmoplegia without ptosis associated with involvement of the right side of the pyramidal tract. He believes that the most important contribution to the etiology of this condition has been derived from studies in embryology. The embryopathophysiologic theory explains the ocular disturbances in these cases. It not only is supported by clinical data but can be verified by experimental procedures (Bagg and Little). The involvement of the right side of the pyramidal tract in the case reported, the author states, becomes intelligible in the light of the experiments of Bagg and Little. These authors constantly found the occurrence of ocular anomalies together with deformities of the extremities, for the abnormal bleb was usually retained on the dorsal side of the organism and nearly always around the anlage of the eyes and the extremities. It is also plausible that a mechanical hindrance in the form of an abnormal bleb situated at the cephalic flexure might injure the anlage of the motor tract and spare the sensory system. These interferences usually occur in embryos of about 7 or 8 mm., or at the fourth or fifth week of embryonic life, at which time the sensory anlage is already ripened and is therefore more resistant to pressure.

Ascorbic and Nicotinic Acid for Edema of Nephrosis.—Daniel reports the rapid correction of the edema of nephrosis of two patients following the administration of ascorbic and nicotinic acids. This leads him to believe that the disappearance of albuminuria and the increase of plasma proteins is not a period of remission which sometimes occurs in nephrosis but is brought about by the administration of the vitamins. He thinks that it is possible that the renal lesion may have a basic

vitamin shortage instead of being entirely the result of infection. In applying this treatment of edema in these cases he based the prognosis on laboratory and physical observations: normal nonprotein nitrogen, normal renal function test, the absence of erythrocytes in the urine, normal blood pressure and normal cardiac action.

Vaccination Against Scarlet Fever.—Strumia investigated the benefits to be expected from vaccination against scarlet fever, employing the scarlet fever streptococcus toxin. He finds that vaccination with scarlet fever streptococcus toxin sufficient to change a Dick-positive reaction to a negative one does not influence in any definite way the content in immune bodies of the serum as far as the fibrinolysins, agglutinins and streptolysins are concerned. Of the thirty-six cases in which determinations of antifibrinolysin and antistreptolysin were carried out before and after vaccination, there was agreement in twenty-five cases. In the other cases the variations before and after vaccination did not agree. A brother and sister in whom toxic hemolytic streptococci were cultured from the throat before the vaccination was begun showed high titer with both antifibrinolysin and hemolysin, which did not change with the vaccination. One of these children was Dick positive and the other Dick negative. In a control group of eight healthy adults studied over a similar period the antifibrinolysin titer showed no change in five, was decreased in one and was increased in two. In the same adult group the antistreptolysin showed no change during the period of observation, all but one being in the normal group. Since the observations were conducted during the late winter and early spring, when streptococcic infections of the upper respiratory passages are common, certain variations in the antistreptococcus properties are to be expected.

Toxicology of Some Glycols.—Laug and his co-workers determined the relative acute toxicities of some glycols and their derivatives and they found that the order of increasing toxicities is as follows: propylene glycol, diethylene glycol, ethylene glycol, diethylene glycol mono-ethyl ether, dioxan and ethylene glycol mono-ethyl ether. Rats, mice and guinea pigs were used for the tests. The rabbits, in comparison with other species, were found to have the lowest lethal dose for diethylene glycol, 50 per cent of them being killed. In fact, the lowest dose that killed some rabbits was the same as the estimated average dose that killed 105 persons. The lethal dose killing 50 per cent of animals in cubic centimeters per kilogram for mice is as follows: propylene glycol 23.9, diethylene glycol 23.7, ethylene glycol 13.1, diethylene glycol mono-ethyl ether 6.58, dioxan 5.66, ethylene glycol mono-ethyl ether 4.31 (concentrated) and 5.2 (diluted); for rats, propylene glycol 21, diethylene glycol 14.8, ethylene glycol 5.5, diethylene glycol mono-ethyl ether 5.54, dioxan 5.17, ethylene glycol mono-ethyl ether 3.46, and for guinea pigs, propylene glycol 18.9, diethylene glycol 7.76, ethylene glycol 7.35, diethylene glycol mono-ethyl ether 3.87, dioxan 3.9 and ethylene glycol mono-ethyl ether 2.79. It seems that small doses of propylene glycol can be safely tolerated by the animal body since it can be oxidized and probably converted to a normal body constituent. In this respect it resembles ethyl alcohol and glycerin. In larger quantities all these substances are toxic and, with the exception of propylene glycol, produce definitely demonstrable tissue injury. After correlating the information in the literature with the results of these experiments, the authors conclude that ethylene glycol, diethylene glycol, ethylene glycol mono-ethyl ether, diethylene glycol mono-ethyl ether and dioxan should be entirely omitted from food and drug preparations and that propylene glycol should be avoided except in minute concentrations.

Bronchopleural Fistulas and Tuberculosis.—Auerbach and Lipstein state that in 1,000 consecutive necropsies in chronic ulcerative pulmonary tuberculosis seventy-eight cases of bronchopleural fistulas were found. Fifteen of the bronchopleural fistulas occurred in previously uncollapsed lungs, fifty-six in the presence of an artificial pneumothorax and seven as a direct result of closed pneumonolyses. The size of the fistula at necropsy varied from 1 mm. to 4 cm. and 73 per cent were present in the upper lobes of the lung. The fistulas were diagnosed clinically in fifty-two cases. Bronchopleural fistulas occurring within six months after the induction of artificial pneumothorax usually ended in a fulminating caseous pneumonia. The underlying pulmonary pathologic condition in cases of bronchopleural fistulas occurring after from one to four years of pneumothorax therapy was that of a chronic pulmonary tuberculosis. Empyemas were present in all but five instances. In these the fistulas developed too soon before death for fluid to collect. Mixed infection empyemas were recorded in twenty-seven instances, tuberculous empyemas occurred in seventeen and the remaining patients either had no aspirations or the reports were inadequate. Healing of bronchopleural fistulas may be temporary or permanent. It may occur because the visceral pleura becomes adherent to the parietal pleura in the region of the perforation or a fibrinous exudate, which later is organized into fibrous tissue, may seal off the opening.

Syphilis.—Humphrey and his associates state that of 6,872 hospital admissions between 1928 and 1937 in which there were positive Wassermann or Kahn reactions, representing 4,517 patients, there were 6,881 syphilitic diagnoses This is not a study of a syphilis clinic or dispensary but of persons admitted to a general hospital in the majority of whom syphilis was an incidental finding and had nothing to do with admission to the hospital From this analysis the incidence of syphilis among the general admissions to the Louisville City Hospital was found to be 13 1 per cent in the Negro patients and 4 1 per cent in the white patients The proportion of men who have positive Kahn reactions in both races is about the same as that of women The greatest incidence of syphilis occurred in early adult life There was a much higher incidence of neurosyphilis and cardiovascular syphilis in men than in women in both races There was a high relative incidence of cardiovascular syphilis in Negro men and of neurosyphilis in white men More than 60 per cent of the patients had no record of being treated for venereal disease Only a small percentage of those treated have had adequate treatment A system has been instituted which provides for persons with incidental positive Kahn reactions They are incorporated into the regular venereal clinic and followed just as though they had come in because of syphilis

Treatment of Gonorrhea in Women.—Notes states that in August 1933 treatment of gonorrhea in women was begun by creating a local reaction and drainage with the omission of antiseptics 1 All cervices with functioning cervical glands were cauterized one or more times with the electrocautery at intervals of two or more months in order to cause local reaction and to elicit better drainage of the active focus 2 The urethral meatus and cervix were treated weekly with applicators saturated with 25 per cent silver nitrate in order to cause local reaction and to favor better drainage 3 Douches of 1 5 per cent acetic acid (vinegar or physiologic) were taken by the patient at home twice daily with a fountain syringe until the cervix was healed and with a pressure syringe (bulb type) after the cervix was healed Of 3,394 women with gonorrhea admitted as new cases to the gynecologic section of the Social Hygiene Clinic of the District of Columbia 705 were discharged as cured by the foregoing method The author concludes that antiseptics should be abandoned in the treatment of gonorrhea in women and that every patient who cooperates can be cured

Sodium Diphenylhydantoinate for Epilepsy.—About a year ago Philips states that fourteen epileptic prisoners at the State Prison of Southern Michigan were given sodium diphenyl hydantoinate as an anticonvulsant The drug, 0 1 Gm, was given three times a day before meals The seizures of all but one patient were controlled by this regimen This one patient continued to have infrequent grand mal attacks at night and his dose was increased to 0 4 Gm daily, that is he also received 0 1 Gm of the drug at 11 at night With the additional dose of the drug there have been no further convulsions None of the patients had previously obtained any benefit from phenobarbital in large doses On sodium diphenylhydantoinate therapy the convulsive seizures have ceased and behavior and attitudes have improved As yet there is no indication that the effectiveness of sodium diphenylhydantoinate is lost or diminishes with time The depression which characterizes patients taking large doses of phenobarbital is noticeably absent with the use of sodium diphenylhydantoinate The drug appears to offer a new hope of assistance in rehabilitation because of its ability to control epileptic seizures without a hypnotic effect

Clinical Significance of Serum Phosphatase.—High concentrations of phosphatase, according to Looney, are found in ossifying cartilage, while only traces are found in the nonossifying type In healing fractures no significant change in the serum levels of phosphatase occurs In conditions affecting bone, the highest values are obtained when there is marked activity either in the formation of new bone or the destruction of old bone Thus in osteitis deformans (Paget's disease), hyperparathyroidism (osteitis fibrosa cystica) and rickets the phosphatase levels may be from ten to twenty times above the normal values However, in osteitis deformans the calcium and phosphorus values are normal, while in hyperparathyroidism the calcium is elevated and the phosphorus is low, and in rickets both calcium and phosphorus are low The severity of the condition in all three diseases is indicated by the extent to which the serum phosphatase is elevated The level of the serum phosphatase gives the most reliable single index for evaluating early and doubtful cases of rickets In hyperparathyroidism the elevated values drop to normal after successful operation Failure of the serum phosphatase to return to normal after operation is therefore an indication that some hyperfunctioning parathyroid tissue was not removed In primary or metastatic osseous cancer the values are usually increased from two to five times the normal Osteogenic sarcomas give rise to

increased phosphatase values if of the osteoblastic type, but not in the osteolytic type. Normal or but slightly elevated values are obtained in chondrosarcoma, giant cell tumor and multiple myeloma. The phosphatase values are normal in bone infections, senile osteoporosis, osteogenesis imperfecta and chronic osteitis. Although the serum phosphatase level does not give a clearcut differentiation in jaundice when the values are moderately increased, one can expect that jaundice in the presence of low values rules out the possibility of obstruction and that extremely high values favor this diagnosis. A fall in phosphatase values during the course of pulmonary tuberculosis indicates a grave prognosis, while an elevation is regarded as a favorable sign.

Rapid Sedimentation Test.—Goldberger states that if drops of blood obtained by pricking the fingertips of different individuals are placed on inverted glass slides, the slides righted and the drops allowed to clot and dry spontaneously, the films, when examined macroscopically by holding them to the light, will show an interesting phenomenon. Some films will give the appearance of a uniform, coarse meshwork. In others, the detail will be fine and there will be a concentration of erythrocytes in the center. The character of the film depends on the degree to which the erythrocytes settle (sedimentation rate) before clotting occurs, coagulation time, degree of agglutination of the erythrocytes (rouleau formation) and rate of drying of the film. Under ordinary conditions the rapidity of drying is unimportant. The rate at which the erythrocytes settle is directly proportional to the degree of their rouleau formation. A slow rate will produce a film fine in detail and uniform in the distribution of the cells, whereas with a rapid rate the rouleaux will be large and the general appearance of the film that of a coarse meshwork. If the coagulation time is rapid compared to the sedimentation rate of the cells there will be a tendency for the cells to be drawn to the center of the film. A very slow coagulation time will merely cause a more uniform distribution of the cells. Fineness or coarseness of general detail, character of the meshwork (if present), presence or absence of central agglutination and presence or absence of a peripheral ring are the criteria for reading the films. With this in mind four groups may be described: + normal, fine detail, no meshwork and gradual transition from periphery to dark central agglutinated mass; + + moderately rapid, the detail being somewhat coarse but uniform throughout, meshwork not noticeable particularly and possibly the beginning of a central agglutinated mass; + + + rapid, coarse detail, the meshwork fine but easily observed and absence of a central agglutinated mass; + + + + very rapid, very coarse detail, definite meshwork and no central agglutinated mass. The test should not supersede regular methods of sedimentation rate, but in the office and at the bedside it is of distinct value. Not only is the test of diagnostic value, the author states, but the slides can be filed and the results checked week by week in cases such as coronary thrombosis, rheumatoid arthritis and salpingitis.

*Effect and Treatment of Arizona Scorpion Stings. M. L. Kent and H. L. Stahnke, Mesa, Ariz.—p. 120.

Treatment of Scorpion Stings.—Kent and Stahnke state that at the Southside Hospital, between April 1930 and May 1937, seventy-five cases of scorpion stings were treated. Symptoms are invariably more pronounced in children. Stings by Centruroides sculpturatus, unless treated at once, are almost always fatal to infants less than 1 year of age. They are extremely dangerous to older children and may cause serious inconvenience to adults. A child stung will cry out with pain. Most generally there is little sign of the sting, in the form either of inflammation or of swelling. The victim soon becomes restless. The restlessness increases to a degree that the child becomes entirely unable to cooperate with attendants. It turns and frets; if placed on its back in bed it does not remain quiet an instant. Frequently it crawls across the bed and attempts to grab its mother or other attendant. The abdominal muscles may become rigid. There may be tonic contractions of the arms and legs. Drooling of saliva begins and the heart rate increases. The temperature may rise to 103 or 104 F. in a patient who will subsequently recover. Cyanosis gradually appears and respiration becomes increasingly difficult, causing a reaction not unlike that observed in a severe attack of bronchial asthma. There may be wheezing, especially on inspiration. Involuntary urination and defecation may occur. In fatal cases the same symptoms become so marked that the child apparently dies from exhaustion. In patients who recover, the acute symptoms subside in twelve hours or less. The foregoing symptoms may be encountered in the adult, but as a rule they are less severe. Numbness is usually experienced at the site of the sting. If one of the extremities has been stung, that member may become temporarily useless. Two cases of temporary blindness have been encountered. Some patients complain of malaise for many days following the sting. A tachycardia lasting two weeks developed in one patient. Morphine if used at all should be used with extreme caution. It has not been found effective in the usual dosage. Barbiturates are more effective and are less dangerous. Bromides in large doses are apparently of value. In cases characterized by severe pulmonary edema, atropine is indicated along with general supportive measures. Compresses of a fairly concentrated ammonium hydroxide solution have been found quite helpful if applied within a few minutes, but if they are applied as late as ten minutes after the sting no apparent benefit is attained. The author states that during the last eighteen months several of the more severe cases have been treated with scorpion serum with results that are encouraging. Symptoms were controlled more rapidly, and when the serum was used death has not occurred.

Weil's Disease in Coal Miners.—Six cases of Weil's disease in South Wales coal miners are reported by Rees, which he believes is the first record of this disease from that area. In each instance it was found that the men worked in wet places, and it was known that the pits concerned were infested with rats. In all six cases the clinical diagnosis was confirmed by positive serologic results. It is important to know that the organism flourishes only in fresh water. If the disease is becoming more common it seems possible that transmission by fresh water bathing may well become a matter for serious consideration. The possibility of spread of infection here is obvious. Again, as pointed out by Alston and Brown, workers exposed to infection may harbor what may be termed a "subclinical" form of the disease. In a series of apparently healthy sewer workers investigated it was found that 20 per cent showed positive serum agglutination reactions for Leptospira icterohaemorrhagiae. These writers suggest that prophylactic inoculation of workers exposed to the risk of infection would seem to be indicated. The disease does not always show itself in its well recognized characteristic form. Meningitis may be the presenting picture, as in the case described by Murgatroyd, who believes that it would be wise to consider a possible diagnosis of Weil's disease in many cases of so-called aseptic meningitis. In half of the cases there may be no jaundice. This being so, in all cases of pyrexia of unknown origin the possibility of spirochetal infection should be considered. In the author's present series of cases the symptoms were fairly typical. One observation of interest was that in three cases the blood pressure was definitely low. This seemed significant in view of the general complaint of weakness. All but one patient recovered, no serum, in effective dose, having been administered to any of the patients. However, to be effective serum must be given early and this series of patients were not seen before jaundice had appeared and the disease was well established.

Weil's Disease in South Wales.—Sladden states that, since the appearance and recognition of the cases of Weil's disease observed by Rees and three others in one locality, active measures have been taken by the colliery owners to rid the mines of rats. No further cases of Weil's disease have appeared in the mines concerned.

Pneumonia with Tuberculosis Treated with Sulfapyridine.—Crawford obtained no improvement from routine treatment of a case of pneumococcic pneumonia superimposed on a pulmonary tuberculous lesion until he gave the patient sulfapyridine on the sixth day of the patient's illness. The initial dosage (1 Gm. every four hours) was not high and as no toxic effects were observed higher doses could probably have been given with safety. The drug was discontinued after five days, which was apparently a little premature in this case, as slight relapse followed. It was easily controlled by further administration of sulfapyridine in the same dosage as before. There was no increase in activity of the tuberculosis as a result of the infection, and subsequent x-ray investigation of the chest revealed a definite improvement in the nature and extent of the lesion.

Visscher-Bowman Test for Pregnancy.—Krieger subjected the urine from 276 pregnant and nonpregnant women to the Visscher-Bowman test. The test was found exceedingly difficult to interpret, since it was frequently difficult to distinguish "powdery" and "flocculent" precipitates in such small volumes of liquid. The results obtained may be divided into the following types: (1) clear solution, (2) hazy solution, (3) slight, fine, dark brown precipitate, (4) heavy, fine, dark brown precipitate, (5) slight brown gelatinous precipitate, (6) dark brown gelatinous precipitate and (7) heavy, dark brown gelatinous precipitate. The last three types, the author states, are the only types in which a definite reaction could be specified, and under such restrictions there were 36 per cent positive reactions among fifty-eight nonpregnant women, 59 per cent positive results among ninety-one women pregnant no longer than three months, 67 per cent positive results among eighty-three women pregnant longer than three months and 55 per cent positive results among forty-four puerperal patients. The incidence of positive results in the pregnant groups is lower than reported by other workers and the number of positive results in the nonpregnant group is much higher. Five specimens of urine from male persons were examined. Two gave negative results, two gave slight precipitates, and a pronounced reaction was obtained with the fifth specimen. The Visscher-Bowman reaction is not an indication of the presence of the hormone of the anterior lobe of the pituitary in urine of pregnant women. The reaction may be due to (1) the presence of reducing carbohydrates, (2) marked concentrations of urinary pigment, with greater possibility of positive reaction in the presence of albumin and (3) the presence of other reducing substances in urine.

Antepartum and Postpartum Azotemia.—Chosson and Dor present the results of a clinical study of azotemia in twenty patients between the ages of 17 and 48, including primiparas and multiparas. The selection made at random was refined by retaining only those who were diagnostically proved to be free from defects of the kidneys and liver. The authors divide their study into two phases: (1) those (eight) in whom azotemia was observed before childbirth with the aid of hypobromite; (2) those (twelve) in whom azotemia was observed after childbirth, to which group those in group 1 were added. The observations indicated an average of 29 per cent, with extremes fluctuating between 20 and 45 per cent (the last a special case), are in accord with generally accepted conclusions and support the view that a lowered azotemia is found in pregnant women. In the second phase of their study, the authors test Estienny's alleged variations in postpuerperal azotemia indicating a high average of 43 per cent during two weeks after childbirth. Blood samples were taken by them on the second, fourth and sixth day post partum and before food ingestion. Their conclusions are that frequently a heightened postpuerperal azotemia occurs, with few individual differences. The apparent discrepancies between their and his observations are explained by the fact that they limited themselves to an observation of six days, while Estienny's extended over two weeks. In evaluating the results, the authors believe that one ought not to underestimate the fact that azotemia post partum is perceptibly close to that of normal physiologic conditions and that urea in the blood reduced during pregnancy because of hydremia tends naturally to normalize itself after childbirth.

Alcoholic Laminar Cortical Sclerosis.—Morel says that the neurogliar architecture may undergo profound transformations. For a number of years he has made systematic studies on the macroglia of the brains from patients with oligophrenia, with dementia praecox, with epilepsy, with dementia paralytica, with alcoholism, with cerebral arteriosclerosis and finally with senile degeneration. In all, the author studied more than 400 brains. The technic that he used for fixation and which he prefers to Cajal's gold chloride-mercuric chloride stain is a modification of the method of Globus. By means of this method he was able to obtain clear pictures of the macroglia in the majority of disorders enumerated. In this report he describes observations on four patients with chronic alcoholism. At the time of death their ages were 37, 51, 52 and 58 respectively. All had been greatly addicted to alcohol and presented signs of grave alcoholic gastritis. In their last years all had signs of alcoholic impregnation with prolonged atypical delirium tremens. Spasticity of the legs rendered walking difficult; there was severe tremor of the hands with mild carphology; also quivering of the face and stuttering. The Wassermann reaction of the blood as well as of the cerebrospinal fluid was negative in all four patients. The examination of the brains revealed that their weights were relatively high. There was subarachnoid edema but no fibrous leptomeningitis typical of dementia paralytica and no granular ependymitis. On the other hand, there was considerable cerebral arteriosclerosis. On microscopic examination, none of the four brains presented senile plaques, nor cellular changes of the Alzheimer type. There were no changes characteristic of dementia paralytica. All four cases presented proliferations of the neuroglia. These are not neurogliar islands or discontinued nests, which in places may have a laminar aspect but which in fact are pseudolaminar; on the contrary, these neurogliar proliferations form a continuous stratum limited to the third layer. Symmetric regions of the brain always show a remarkable similarity with respect to the extension and the intensity of this proliferation. To be sure, not all cerebral regions show it with the same clarity. It is especially pronounced in the frontal lobe, but in the ascending frontal convolution it is not as noticeable as in the other frontal convolutions. It is again more pronounced in the parietal region but toward the occipital lobe it tends to disappear. As regards the condition of the neuroglia in this third layer, the author says that the astrocytes in the third layer have numerous thickened vascular pedicles and they are stretched out. Thus it may be said that there is hyperplasia, hypertrophy and alteration of the astrocytes in the third layer. The microglia of the third layer likewise has undergone changes. Although in other parts of the cortex it is relatively fine and delicate, in the third layer it is coarse. The alterations presented by the nervous cells of the third layer are not particularly characteristic. The author suggests for the described cerebral modification the term "alcoholic laminar cortical sclerosis."

"Agastric" Anemias. R. Leroux and E. Vermes.—p. 241.
*Hemopathies Caused by Benzene. F. Mignolet.—p. 268.

Hemopathies Caused by Benzene.—Mignolet was able to observe for many months a number of cases of benzene intoxication that occurred in a heliogravure workshop where benzene was used as a solvent for the ink. The benzene used is not chemically pure but is a mixture containing variable quantities of xylene and toluene and some impurities. The solvent that caused the accidents described here contained 80 per cent of benzene and nearly 20 per cent of toluene. The onset of the poisoning is not characteristic. The patients complain first of disorders of a nervous type, such as vertigo, headaches and abnormal excitation. Soon anorexia and somnolence develop, then asthenia and fatigability and often muscular cramps. Frequently the patients appear emaciated and pale. Cardiac involvement is indicated by rapid pulse, palpitations and arterial hypotension; respiratory symptoms are dryness of the throat, cough, dyspnea, suffocation and sensations of thoracic constriction; disorders of the digestive tract are anorexia, hypoacidity, nausea, vomiting, constipation and hepatic congestion; hemorrhagic symptoms are petechiae, ecchymoses, epistaxis, gingival bleeding, hemoptysis and menorrhagia. Moreover, many patients have attacks of fever, particularly at the time of relapse. The author observed twenty-six cases of benzene intoxication; fourteen were grave and necessitated prolonged inactivity (eighteen months and more). One patient, a man aged 29, died with symptoms of severe anemia and agranulocytosis in spite of repeated blood transfusions. In the second part of this report, the author shows that benzene is a poison of the blood, describing its effects on the various hematic elements. Regarding the therapy, he says that he obtained favorable results with the injection of liver extracts. Extracts administered by mouth only improved the appetite but were without action on the hemogram. However, the transfusion of citrated blood proved to be the most effective of all therapeutic procedures. Ephedrine and strychnine proved helpful against the asthenia. The author thinks that, in order to prevent poisoning with benzene, workers who have to use it must be carefully examined. Persons with cardiac, anemic, hepatic, renal and thoracic disorders or with a predisposition for them should be rigidly excluded from occupations that necessitate contact with benzene. Persons who do work with the substance should be examined at regular intervals (every two or three months), the examination to include a complete hemogram. Strict hygienic measures should be enforced in the shop (washing of hands, wearing of masks, proper ventilation and so on). In the conclusion, the author emphasizes that thrombopenia and prolongation of the time of coagulation are signs of alarm, but granulopenia is already a sign of intoxication. The anemias of benzene intoxications are usually hyperchromic aplastic anemias.

Scarlet Fever Streptococci.—Wyler says that although it seems definitely established that streptococci play a part in the pathogenesis of scarlet fever, it is as yet not certain whether scarlet fever is caused by a special type of streptococcus or whether it represents an especial reaction of the organism to the streptococcic infection. He reports a case in which it proved impossible to differentiate between streptococcic sepsis and scarlet fever. A boy aged 10 sustained lacerations and contusions below the left knee when he fell into a pit filled with liquid manure. In spite of excision of the wound and of the administration of tetanus serum, fever and symptoms developed on the basis of which meningitis and tetanus were thought of. Later, the diagnosis wavered between tetanus and sepsis, but tetanus could be excluded on the basis of the blood picture. There was no typical scarlet fever, no redness of the throat, no angina and no exanthem. A blood transfusion that was given to overcome a serious circulatory impairment effected a rapid improvement in the circulation and it was followed by the appearance of the circumoral pallor and the strawberry tongue; that is, by symptoms typical of scarlet fever. The questions raised by this case are: 1. Was the causal organism in this case a specific scarlatinal streptococcus; that is, did the boy have a fulminant traumatic scarlatina? 2. Was the reactivity of the organism such that it reacted to the streptococcus in the wound with scarlet fever? 3. Was the disorder simply a streptococcic sepsis which was modified by the transfusion into a scarlatina-like process? These questions are undecided, but the author is inclined to accept the latter version, namely that a severe septic process, caused by streptococci, took on a scarlatina-like course after a blood transfusion.

Urethritis from Enterococcus.—Rivelloni and Spanedda point out the importance of nongonococcic urethritis. They made observations on a group of fifty-six patients (forty-eight men and eight women) who were suffering from enterococcic urethritis. The condition may be either primary, which follows sexual intercourse, or secondary, which follows a controlled gonococcic infection. In either form the period of incubation lasts for ten or twelve days, the symptoms are mild and the urethral secretion is scanty, mucous, thick and yellow. The urogenital apparatus is not involved. In urethritis in men the only urethroscopic observation consists in the presence of moderate diffuse hyperemia at the anterior urethra, which is milder in the primary form than in the secondary form. The posterior urethra in men and the female urethra do not show urethroscopic changes. The bacteria isolated from the urethral secretions belong to type C of Koch's bacteria and dissociate into the S and R phases. The infection does not heal spontaneously. The authors reproduced, experimentally, enterococcic urethritis in various groups of volunteers. They succeeded by injecting 3 cc. of a pure culture of Enterococcus in the normal urethra and also by making passes of the experimental infection. In women the condition, either clinical or experimental, develops in association with enterococcic cervicitis. The authors found that Enterococcus in vitro is resistant to sulfanilamide preparations and that the latter preparations, when they are administered alone, whether by mouth, in intramuscular injections or in local applications, fail to control the clinical and experimental infections. Autovaccines administered to the patients also fail. The author obtained satisfactory results from a combined treatment which consisted in administration of sulfanilamide by mouth, local instillations of a 0.25 or 1 per cent silver nitrate solution every day, for the duration of three or five minutes and lavages, every other day also, with a 1:5,000 potassium permanganate solution or a 0.1:1,000 mercury oxycyanide solution. Patients in poor general condition were given preparations of arsenic or phosphorus. The treatment must be given over a long period of time in order to prevent possible recurrences.

Cancer and Tuberculosis of Larynx.—In a group of seventy patients suffering from primary cancer of the larynx and seen at the Clinica Oto-Rino-Laringologica of the University of Bologna, Rossi observed four who had cancer of the larynx associated with laryngeal tuberculosis. The four patients ranged in age from 45 to 57. Only one patient was under 30. The diagnosis of the diseases was made by microscopic study of the tissues, which were removed by biopsy, and in two cases also by study of the larynx, which was removed by laryngectomy. Metastases were not present in any of the cases. According to the author there is no antagonism between cancer and tuberculosis in the same organ. The larynx is a structure which may be the seat of either tuberculosis or cancer in the presence of or preceding the other disease. The most frequent forms of laryngeal cancer in tuberculosis are (1) cancer of the normal larynx complicating pulmonary tuberculosis, (2) cancer of the tuberculous larynx and (3) primary laryngeal cancer with secondary development of laryngeal tuberculosis. A clinical diagnosis is difficult. The diagnosis is made by biopsy. When the patients are in good general condition and the disease is in its early phase of development a laryngectomy may give satisfactory results. However, the author calls attention to the fact that either tuberculosis or cancer of the larynx alone is grave. Consequently the association of the two conditions is still more grave. Moreover the evolution of the two conditions in association will depend on several factors, such as for instance the individual resistances, the phase of evolution and the more or less malignant type of the disease and the administration of early treatment.

*Variations of Chloremia from Administration of Ascorbic Acid. C. Pegoraro and G. Comi.—p. 623.
Participation of Nervous System in Diseases of Reticulo-Endothelial System. L. Greco.—p. 641.

Chloremia from Ascorbic Acid.—Pegoraro and Comi made determinations of chloremia in a group of thirty-six persons including normal persons and patients who were suffering from different diseases. The determinations were made on fasting persons before and after the administration of an intravenous injection of 0.5 Gm. of ascorbic acid. They were performed at intervals of one hour. The authors found that chloremia diminishes after the administration of ascorbic acid. The lowest figures of the curve of chloremia correspond to the third hour in the course of the test, after which chloremia slowly returns to high figures, which however are lower than those which existed before administration of the acid. If the test is repeated one week later during which the patients receive daily intravenous injections of 0.5 Gm. of ascorbic acid, the figures of chloremia during fasting and before administration of the acid on the day are lower than those which were observed in persons in the same condition in the test previously made. The authors carried on determinations of diuresis and of the elimination of chlorides through the urine in a group of eight patients who were suffering from different diseases. The determinations were made on the total amount of urine which was eliminated in the course of three days before and after the administration of ascorbic acid in daily doses of 0.5 Gm. The authors found that both diuresis and the elimination of chlorides through the urine increase from the treatment. Therefore they conclude that the administration of ascorbic acid in doses of 0.5 Gm. induces diminution of chloremia and increase of diuresis and chloruria.

Bilateral Carotid Tumors.—The relatively recent knowledge of tumors of the carotid gland, according to Marangos, dates from their description by Marchand and Paltauf. The rarity of the lesion may be judged from the fact that MacCarthy and Bevan were able to collect from the literature up to 1929 not more than 131 cases. Rankin and Wellbrock collected 196 cases in world literature up to 1932, while sixteen more cases are to be found in recent contributions. Bilateral occurrence of the tumor was reported twice, once by Rankin and Wellbrock and once by Lund. The author reports a successful operative removal by Makkas of bilateral carotid tumors in a girl aged 23 at the Red Cross Hospital in Athens. The tumor on the right side was noticed by the patient five months after the removal of the tumor on the left side and was operated on three months later. Both tumors were removed without damaging or ligating the common carotid artery, either of its two main branches or the vagus nerve. Both tumors presented on a microscopic examination identical structure, that of a paraganglioma or struma of the carotid gland. The paragangliomas represent hypertrophy of the cellular structure of the carotid. They develop at the site of bifurcation of the common carotid artery, grow slowly and seldom undergo malignant transformation. The far more rarely occurring neurofibromas develop from the nervous elements of the carotid plexus and are, as a rule, malignant. The surgical removal of the tumor, while theoretically most desirable, is hazardous and technically difficult. It carries with it the dangers of postoperative bleeding, paralysis of the hypoglossus nerve, Horner's syndrome and syncope or sudden death due to the irritation of the carotid plexus. In a considerable proportion of the cases there arises the necessity of ligating the common carotid artery. The latter procedure is associated with an immediate mortality of 32 per cent, according to Hartmann. The author is of the opinion that removal of a small tumor without ligation of the common carotid artery is possible in not more than one third of the cases and that in this group the mortality is about 5 per cent. The postoperative complications following ligation of the artery are hemiplegia and paralysis of the vagus, the sympathetic and the hypoglossus. Roentgen therapy is not successful because of the lack of radiosensitivity on the part of the mature cells of the paraganglioma. Barbier and Hartmann suggest exposure of the tumor and an immediate biopsy. If the tumor is benign, as much of it as is possible is removed, and the remaining tissue is subjected to later roentgen irradiation. Only in the case of a malignant growth do they feel that ligation of the common carotid artery is justified.

Calcium Content of Blood.—Linneweh reports his observations of hypocalcemia secondary to hypalbuminosis and indicates a new regulatory blood mechanism. The diseases studied are etiologically unrelated, show no spasmophilia (except for a sporadic case) and are characterized by an albumin deficiency with a tendency to edema and by hypocalcemia. Clinical experiences, the author says, clearly prove that certain diseases accompanied with tetany are caused by a calcium deficiency but have yielded only meager information on the regulatory process of the calcium content. By means of dialysis and ultrafiltration, the total calcium content of the blood can be determined in its component parts: diffusible (the larger part positive, the smaller electrically neutral) and nondiffusible. Normally, the diffusible portion is said to amount to from 5 to 6 mg. per hundred cubic centimeters. This proportion is lowered when the parathyroid glands are removed. Reduction is also observable in cases of pure tetanus. According to the author, probably other regulatory mechanisms of a hormonic and nervous nature besides the parathyroid glands exist and affect the total calcium content, but their effects do not seem to be important. Hypocalcemia is found in other diseases that do not show tetanus and spasmophilia, but there is still much doubt as to what extent the changes in the calcium content are really characteristic of these diseases and what the true cause is. In only a few cases were the diffusible and nondiffusible portions of the reduced calcium content studied separately or was a satisfactory explanation of the calcium reduction given. Among the diseases studied by the author showing hypalbuminosis are war edema, pancreas deficiency, nephrosis, pericarditis and ascites. In all these diseases a regular relationship is observable between the calcium level and the albumin level. Because of the practical absence of tetany, the author does not regard dysfunction of the parathyroid glands as causative of hypocalcemia secondary to hypalbuminosis but of physiochemical relationships, a portion of the calcium being combined with and dependent on albumin in the blood. It may be accepted as scientifically demonstrated that the nondiffusible portion of the calcium is dependent on the albumin. Often the percentages obtained by ultrafiltration, he says, for the dependency of calcium on albumin were found to be higher than those obtained by dialysis. The clinically ascertained parallelism of fluctuation between the calcium content and the albumin content indicates a close connection between the two substances. This connection is so close that not only the ultrafiltrable but also the nonultrafiltrable portion of the calcium shows a decrease when the albumin content decreases. The author, therefore, regards the designation of diseases as "hypocalcemias secondary to albuminosis" as terminologically justified. He sees a twofold value in recognizing this class of disease: 1. One need not at once infer increased spasmophilia from decreased calcium content. 2. The reduction of the calcium reserve that is dependent on the albumin content limits the efficiency of the regulatory mechanism. The appropriate therapy is to restore the normal calcium reserve. Removal of hypalbuminosis increases the ability of the calcium to combine. Normalizing of the diffusible and nondiffusible portions of the calcium is best attained by a diet rich in albumin.

Vitamin C Content of Human Brain.—Diehl and Neumann report the use of methylene blue (as applied by Bonsignore and Martini) to determine the vitamin C content of the various portions of the brain in nineteen adults between the ages of 21 and 84 and one infant aged 7 weeks. Clinical research emphasized the difference between the vegetative and nonvegetative brain centers. The anatomic procedure is indicated for the portions of the brain studied. The greatest vitamin C content was found in the tuber cinereum, medulla oblongata and hypophysis in the order given, the lowest in the cerebellum, corpus callosum and cerebrum, ascorbic acid being represented in the extremes of 1.2 mg. and 30.5 mg. per hundred cubic centimeters in the adult brains and of 48 mg. per hundred cubic centimeters in the hypophysis of the infant brain. The authors suggest that the difference in vitamin C content between the high and low group is due to the difference in vegetative centers, Bodechtel's investigations having already established the vegetative significance of the brain portions rich in vitamin C. On the other hand, according to the authors, the brain portions with lowest content have clearly little to do with vegetative functions. Results relative to the hypophysis invite the conjecture that the hypophysis of healthy persons contains the highest proportion of vitamin C but that, whenever a deficiency of this vitamin occurs in a person, the hypophysis suffers a much earlier and more

incisive curtailment of its functions. The interpretation of the results follows the conclusions of Tonutti that a high vitamin C content of an organ is indicative not of a process of "storing" vitamin energy but of the immediate active demands made by the system on it. The more active an organ is, the more vitamin C it contains. The portions of the brain that are the last to cease functioning are connected with the vegetative centers and as the most active are richly supplied with vitamin C. This interpretation, the authors believe, also accounts for the fact that the brain portions intermediate between the high and low groups show so great a fluctuation. Manifestly, shortly before life becomes extinct and varying according to the person and the pathophysiologic picture, some of the intermediate brain portions flicker into a final intensity of function at one time or another. On the other hand, the lowest of these portions in the authors' rating scale, the cerebrum, reduces its functioning to a minimum long before death. The conclusions of others pertaining to the relations existing between age level and vitamin C content have been confirmed in this investigation.

*Value of Prophylactic Administration of Prontosil in Manual Detachment of Placenta. A. Pohl.—p. 346.

Prontosil Prophylactically in Manual Detachment of Placenta.—A review of the literature on the prophylactic administration of sulfanilamide preparations in septic complications of the puerperium discloses favorable results, but Pohl admits that it is unnecessary to administer sulfanilamide to every puerperal woman. Manual detachment of the placenta, which is one of the most dangerous obstetric operations, justifies the prophylactic use of sulfanilamide. The prophylactic treatment employed by the author consisted in the intragluteal administration of 0.25 Gm. of prontosil. This prophylaxis was used in forty-six cases of manual detachment of the placenta. Comparing the cases of manual detachment of the placenta in which prontosil prophylaxis was used with those of previous years in which this form of prophylaxis was not used, it was found that the women who were given this treatment could be discharged from the clinic as early as after spontaneous delivery except in the cases in which severe anemia necessitated a longer stay. None of the thirty-six women in whom manual detachment was the only operation developed endometritis or thrombophlebitis when prontosil prophylaxis was employed, whereas in the same number of cases in which prontosil prophylaxis was not employed each of these complications developed twice. In the remaining ten of the aforementioned forty-six cases, the manual detachment was performed following other vaginal operations. A comparison with the same type of cases in which prontosil prophylaxis was not employed again proved the efficacy of the prontosil prophylaxis. In general, it can be said that manual detachment of the placenta as the only operation is less dangerous than when it is combined with other operations. The author thinks that all puerperal women who are threatened with septic infections should be given immediately an intragluteal injection of 0.25 Gm. of prontosil. Following this, they should be given three times daily, for four days, one tablet of prontosil. The author thinks that this prophylaxis will reduce not only the mortality but also the puerperal diseases likely to result in sterility.

*Determination of Blood Group as Sedimentation Reaction. F. Sander and Meta Sander.—p. 268.

Blood Group Sedimentation Reaction.—The blood group sedimentation reaction described by the Sanders has the aim to measure differences in the intensity and in the time factor of the isohemagglutination better than was possible with the former methods. The authors point out that it has been investigated repeatedly whether connections exist between the sedimentation speed of the erythrocytes and the blood group to which the erythrocytes belong. With the ordinary technic of blood sedimentation, the authors were unable to detect group specific differences in the sedimentation. However, the conditions become quite different when the erythrocytes are brought in contact with serums that are antagonistic to the group; that is, when the erythrocytes of groups A and AB are combined with anti A (beta) or O (alpha, beta) serum or when B or AB erythrocytes are combined with B (alpha) or O (alpha, beta) serums. In these cases, the sedimentation speed is enormously increased; within a few minutes, the erythrocytes may drop from 200 mm. (Westergren) to 10 per cent of the height of the column, a drop of 180 mm. This rapid sedimentation is preceded by a more or less coarse conglobation of the erythrocytes, which is similar to that observed in the determination of the blood groups. This conglobation of erythrocytes is the result of an agglutinin fixation by the erythrocytic receptors. The authors suggest the following method for the determination of the blood groups by means of sedimentation: Several cubic centimeters of venous blood is withdrawn and the serum is separated from the erythrocytes by centrifugation. Then 0.6 cc. of the serum to be examined is placed into each of two small test tubes and is mixed with an equal amount, that is, 0.6 cc. each of a suspension of test erythrocytes, of A or B erythrocytes in physiologic solution of sodium chloride (dilution 1:10), and this mixture is immediately drawn up into a Westergren pipet. Then, frequently after a few seconds, the strong conglobation of erythrocytes is observable and this is followed by a rapid sedimentation. The results are then read in the manner customary for the blood group test. That is, if sedimentation has taken place in both serum specimens, with A as well as with B test erythrocytes, it is an O (alpha, beta) serum; if sedimentation is produced only with A test erythrocytes, it is in the first case a B (alpha) serum and in the second case an A (beta) serum, and if there is no sedimentation at all the serum in question is of the AB type. The authors further describe a number of factors that may eventually be of influence on the course of the reaction and direct attention to two entirely different types of sedimentation, the rapid and the slow type. Finally they suggest the possibility of an "analysis" of the sedimentation of the erythrocytes by means of the sedimentation method.

Heredity of Thrombo-Angiitis Obliterans.—On the basis of the assumption that the mechanisms of the pathogenesis of rheumatism and of thrombo-angiitis obliterans are related, Reichert decided to investigate whether in families of patients with thrombo-angiitis obliterans there is an increased incidence of rheumatic diseases. Moreover, since thrombo-angiitis obliterans is a vascular disease with a tendency to the formation of thrombi, he gave his attention to the occurrence of other vascular disorders such as atherosclerosis, apoplexy, thrombosis, embolism and infarct. Starting with patients who had thrombo-angiitis obliterans, he made studies on three extensive family groups. He noticed a high incidence of diseases of the rheumatic type in general and of articular rheumatism in particular. He stresses that the observations on these family groups provided new proofs for the hereditary origin of the hyperergic mode of reaction and of rheumatism. Observations on two of the families indicated that, besides the inferiority of the connective tissue system, the susceptibility of the vascular apparatus is a decisive factor in the pathogenesis.

Narrowing of the Lung Arteries Due to Incrustation of Lung Hilus.—Two cases of interest in forensic medicine are reported by Orsós in which circulatory trouble was found to be the sole cause of death, leading to degeneration of an overburdened right heart. Both patients were over 60 years old at the time of death. Careful observation of the lungs revealed an obstruction at the lung hilus at the secondary branches of the lung arteries or somewhat below. The obstruction, in the shape of a funnel or hourglass, was caused by the shale-like incrustation of the enlarged hilus lymph nodes and their surroundings. As a result of the incrustation, the interstitial tissue of the hilus, together with the lymph nodes, changed into a hard tissue-plaster, in which the blood vessels were embedded. Microscopic examination of one of the cases revealed that the wall of the narrowed secondary branch of the lung artery was of varying thickness. It was even missing on one side, granulation tissue taking its place, narrowing in its turn the already narrowed passage.

*So-Called Metastasizing Adenomas. S. A. Kholdin.—p. 153.

Tumors of Lips.—According to Shanin, fifty-six cases of tumors of the upper lip and 681 of the lower lip were treated at the Oncologic Institute of Leningrad between 1926 and 1936. Tumors of the upper lip were encountered more frequently in women than in men. About one third of the tumors of the upper lip were either benign or precancerous lesions. The greater variation in their histologic structure, as compared with that of the tumors of the lower lip, is to be explained on the basis of a derivation from a greater number of embryonic elements. The duration of the lesion at the time of admission was essentially the same for the second five year period as for the first. The author advocates radical removal of the precancerous lesion extending 0.5 cm. into healthy tissue. In the surgical removal of tumors of the upper and the lower lips inclusion of 1 cm. of healthy tissue for the early lesions and of 1.5 cm. for the more advanced lesions is advocated. The follow-up cases thus treated showed 80 per cent of cures for a considerable time. Experience with irradiation showed the necessity of increasing the dosage to 1.5 millicuries for each square centimeter of irradiated surface when radium implantation was used, and to 2 or 3 millicuries for each square centimeter of irradiated surface when radium was applied at a distance of from 1 to 2 cm. The dose was likewise increased to 3,000 or 4,000 roentgens when the fractional method was applied. The surgical removal of tumors of both lips is applicable to cases in which the operation can be easily carried out and in which it will not be followed by a disfiguring scar. Electrosurgery is indicated for lesions developing on the basis of leukoplasia or leukokeratosis. Recurrences involving complicated plastic procedures for their removal were treated instead with radiation. Radium implantation therapy resulted in 70 per cent of cures and radium application in 61 per cent. The difference in all probability was due to the fact that the implantation method was applied to the earlier cases. The implantation method gave best results in tumors in the second or third stage, while radium at a distance gave best results with tumors in the first stage. Radium implantation proved to be the best method in recurrences. Regional metastases were treated by operative removal in 266 cases and by roentgen therapy in fifty-two. Preoperative roentgen irradiation increased the effectiveness of the operative removal. The operation for regional metastases involved the removal of all submaxillary connective tissue along with the salivary glands and lymph nodes from both sides. Complications of inflammatory nature exerted an unfavorable influence on the malignant process.

So-Called Metastasizing Adenomas.—The formulation of a satisfactory classification of tumors of the thyroid, according to Kholdin, is difficult because of a number of tumors of a transitory type and because of lack of correspondence in some cases between the microscopic structure of the neoplasm and its clinical course. To this group belong the rather infrequent but interesting variety of so-called metastasizing adenoma first described by Cohnheim in 1876. Simpson has collected seventy-seven cases up to 1926. Only those adenomas the microscopic structure of which as well as the microscopic structure of their metastases do not contain carcinoma cells are to be included in this group. The microscopic structure of the metastatic nodules resembles almost entirely those of the primary tumor. The predominating type is one made up of small follicles lined with high cuboidal or cylindric epithelium and containing colloid. Among the microscopic characteristics which differentiate this tumor from ordinary benign adenomatous colloid goiter, the author stresses the invasion of the capsule of the adenoma by the epithelial elements and more particularly their invasion of the blood vessels. The author suggests that the term "angiophilic" more accurately describes this adenoma than the term "metastasizing" or "malignant." These tumors, in the opinion of the author, occupy an intermediary position between benign and malignant neoplasms of the thyroid but are to be considered, because of the tendency to invasion of the blood vessels, as potentially malignant. The author feels that all new growths of the thyroid not associated with sexual maturation or endocrine disturbances should be removed and examined microscopically. Invasion of the blood vessels may be observed by the naked eye in the course of a thyroidectomy. Such vessels should be ligated and resected; if necessary the internal jugular vein should be similarly treated.

Transplantation of Tissue for Therapeutic Purposes.—According to Filatov, partial superficial corneal transplants taken from a cadaver and conserved for from two to seven days at a temperature of from 2 to 4 C. gave better results than when fresh corneal tissue was used. Excellent results were obtained in the last two years in seventeen cases in which the original corneal transplant began to turn opaque. Partial corneal transplants from a cadaver placed at the margin of the opaque transplant rendered it once more translucent. The author treated a variety of inflammatory processes of the cornea with this method and obtained striking therapeutic effects. In eight cases of parenchymatous keratitis of syphilitic origin, the process was arrested in from eight to ten days and the regressive period was considerably shortened. Striking results were likewise obtained in cases of herpetic keratitis, tuberculous keratitis, keratoconus, trachomatous pannus, tuberculous choroiditis and pigmented choroiditis. The method was applied in cases of lupus vulgaris of the face, in tuberculous ulcers, burn scars, scleroderma, psoriasis and duodenal ulcers. In cases other than those involving the eye, the author used various tissues removed from a cadaver, such as skin, labial mucous membrane or blood vessel wall. These were kept for from five to seven days at a temperature of from 2 to 4 C. The

therapeutic effect manifested itself either in rendering the tissue translucent and elastic (cornea), in absorbing a scar, or in stimulating regenerative processes (ulcers). This effect was obtained with autoplastic as well as with homoplastic transplants. The author does not possess as yet sufficient material to determine the relative value of the autotransplant. He attempts to explain the therapeutic effect of skin taken from cadavers and kept refrigerated for several days by assuming that the tissue thus kept is still alive but that in the early stages of its mortification it contains certain products of decomposition capable of acting as catalyzers. They are probably related to the stimulating substances in traumatized tissues, as pointed out by Haberland, and to the "necrohormones" of Caspari appearing during the early stages of decomposition of dead tissue.

Pulmonary Cancer and Tuberculosis.—Faynshmidt and Karliner personally observed 115 cases of primary bronchogenic carcinoma in an attempt to establish the possible etiologic relationship of pulmonary tuberculosis to pulmonary cancer, the effect of one on the other and their differential diagnosis. Hunter's as well as Rokitansky's theory of antagonism of the two processes and their incompatibility in the same organism is refuted by the more recent observations, according to which the coexistence of the two was observed in from 2 to 30 per cent. Most observers emphasize that it is the inactive, fibrous type that is seen in these cases. In the authors' material the coexistence of primary bronchial carcinoma with tuberculosis was observed in 25.9 per cent of the cases. The tuberculous process was represented by more or less healed fibrous foci. There apparently existed no etiologic relationship between the two. They have observed in 10.4 per cent of their cases a combination of bronchial cancer with active open forms of tuberculosis. These lesions represented either a flaring up of old reinfections with a breaking down and the appearance of tubercle bacilli in the sputum as a result of the direct effect on it of a new growth, or an activation of an old process as the result of weakening of the organism by the malignant process. The two processes develop most frequently in the same lung but not in the same localization.

Boron as Antiepileptic.—In order to determine the value of boron as an antiepileptic, Verjaal employed it in 100 adults with epilepsy who reacted inadequately to large doses of bromine and phenobarbital or similar substances. He substituted boron preparations for a part of the other medicaments. He always gave the boron preparation in combination with phenobarbital, at first in a combination suggested by Willemse, later in the following combination, which caused less complications: phenobarbital 0.075 Gm., sodium borate 0.500 Gm. and boric acid 0.500 Gm. Powders made up of this combination were given from one to three times a day and in exceptional cases four times. Boron preparations may be given in fluid as well as in powder form, but when given in combination with phenobarbital the powder form is to be preferred. The epileptic patients who were treated with this combination previously had had several epileptic seizures weekly, in spite of the regular use of large doses of phenobarbital. The combined administration of phenobarbital and boron preparation arrested the seizures completely in thirteen patients, and in twenty-seven patients the number of seizures was reduced to less than one third. Among the undesirable complications that may result from medication with boron preparations the author mentions exanthem, gastrointestinal disturbances, increase in temperature, albuminuria, alopecia areata and emaciation. Discussing these complications and their causes, the author points out that, since boron preparations are a constituent of some popular reducing remedies, the physician should consider the possibility of boron poisoning when patients exhibit some of the aforementioned toxic symptoms. The diagnosis of boron poisoning can be based on the presence of boron in the urine. Studies on the metabolism of boron preparations suggested that their favorable effect on epilepsy can be ascribed to their action on the biologic condition of the organism.

*Serum from Convalescents in Combating Mortality from Measles. W. A. Timmerman.—p. 1346.
Prophylaxis of Measles. H. I. de Ruiter.—p. 1356.

Convalescent Serum in Measles.—Timmerman says that, although the mortality from measles has somewhat decreased in recent years, measles is still comparatively dangerous. A table which indicates the mortality per hundred thousand of population for measles, scarlet fever, whooping cough and diphtheria shows that the mortality from measles comes right after that of whooping cough and is much higher than the mortality from scarlet fever and diphtheria. The mortality is greatest among children less than 5 years of age and it is therefore important that these children be given protection. As a rule it is an older child of a family, one going to school, who first comes in contact with measles, but fortunately these older children are not so much in need of protection. On the day on which the exanthem appears in the first child, that is, when the definite diagnosis is made, the other children should be subjected to prophylactic serotherapy. The author emphasizes that protection is especially important for children less than 3 years old and for all children of any age who have another disorder. He reports the efficacy of convalescent serum in ninety-eight children, some of whom lived in home surroundings and some in various institutions (children's hospitals, sanatoriums and so on). In twenty-three cases partial protection was aimed at and it was accomplished in twenty-two cases; in one case the resulting protection was complete. In seventy-five cases complete protection was the purpose, which was successful in fifty; in twenty cases a slight morbilloid resulted, in five no influence of the serum on the course of the disease was seen. A table which lists the dosages employed reveals that for complete protection from 3 to 12 cc. is given, the larger doses being administered to older children and in the later stages of incubation. In remarks about the possibility of substituting placental extract for convalescent serum the author says that the placental extracts are likely to cause undesirable complications and that, until they have been further improved, convalescent serum is to be preferred.

Treatment of Abortion.—Holtz collected and analyzed 2,718 cases of abortion, 1,372 of which were reexamined at the end of four years of observation. Regarding the early abortions, that is, those developing during the first three months, the author says that in the uncomplicated cases without severe hemorrhage the immediate as well as the late results were better after active treatment: infection spread less frequently, the mortality was lower, the patients were bedfast for a shorter period and sterility followed less often than was the case after conservative treatment. The better results of the active treatment were especially noticeable in febrile cases. The evacuation after a prolonged course was followed comparatively often by a spreading infection, development of secondary anemia, prolonged rest in bed and sterility. Evacuation at the feverish stage did not seem to impair the results of active treatment, but to a certain extent abundant bleeding had an aggravating effect. Summarizing his observations on late abortions, that is, on those occurring between the fourth and seventh month of gestation, the author says that the result of expectant treatment was good both in feverish and in nonfeverish cases. In the majority of cases fetus as well as placenta passed spon-

taneously and completely In the cases in which placental retention occurred, the result of active treatment was more satisfactory (lower morbidity and shorter period in bed) than that of conservative treatment In these cases likewise the result of evacuation after a prolonged course was less satisfactory These observations show that in cases of early abortion without complications the treatment should be active, in cases of late abortion, on the other hand, it should be expectant, except in placental retention, in which case evacuation should be induced

Roentgenologic Diagnosis of Placenta Praevia—Petersen reviews the method of the roentgenologic diagnosis of placenta praevia, which was described by Ude and Urner in the *American Journal of Obstetrics and Gynecology* **29**:667 (May) 1935 The method is a cystography, that is, 40 cc of a 12.5 per cent solution of sodium iodide is instilled into the bladder after it has been emptied Petersen says that he used this method with satisfactory results in several cases In the presence of placenta praevia a free space appears in the roentgenogram between the fetal head and the bladder The method permits the diagnosis of placenta praevia centralis and partialis and it confirms the absence of placenta praevia in the cases in which there is no space between the fetal head and the maternal bladder

Studies on Duration of Birth in Finland Rapidity of Opening of Uterine Os, Time of Rupture of Bag of Waters and Rapidity of Passage of Head Through Birth Canal A M Ritala —p 63

Estrogen in Treatment of Menstrual Disturbances.—Anker treated seven cases of menorrhagia, including six of the juvenile type, with large doses of estrogen In two cases the cycle became regular after the treatment, the loss of blood being of normal strength and duration In three others the treatment was followed by a decrease in the strength and the duration of the hemorrhages, but the cycle did not become regular, on the contrary, amenorrhea of several months' duration developed before menstruation set in again In two cases the menorrhagia persisted after the treatment but the severity was lessened One of the latter cases was not of the juvenile type Curettage in three of the cases of juvenile menorrhagia showed the usual histologic picture of that disease, namely glandular hypoplasia of the endometrium with twisted glandular tubes of increased number, depth and width The author concludes from this that the mucosa is influenced by the corpus luteum hormone rather than, as is usually assumed, that the function of the corpus luteum is deficient in these cases Consequently the disorder should be treated with estrogen rather than with progesterone In five cases of secondary amenorrhea or oligomenorrhea the author gave estrogen either alone or in combination with progesterone Three patients responded to the treatment with menstrual bleeding, in two cases the infantile symptoms were improved and one woman, who had been sterile for a year, became pregnant

*Uratic Arthritis K Brøchner Mortensen —p 51

131: 101 172 (March) 1939

*Uratic Arthritis K Brøchner Mortensen —p 101

Uratic Arthritis—On the basis of the literature and on his observations in the twenty-six cases reported, Brøchner-Mortensen discusses the diagnosis of uratic arthritis A typical history and acute attacks, he says, are the most certain aids in diagnosis Subcutaneous uratic tophi, verified by the murexide test, while pathognomonic for uratic arthritis, are inconstant and are usually a late symptom, roentgenologically demonstrable defects in the bones are of more frequent occurrence and appear earlier but they are not pathognomonic Hyperuricemia, which occurs in about two thirds of the cases and is almost always present when the condition has lasted for some years, also appears in other disorders The amount of endogenic uric acid eliminated is the same as in normal persons The renal function measured by the creatinine and urea clearance is normal in most cases After intravenous or oral purine loading, an increase of at least 50 per cent, usually considerably more, is seen in the urea clearance in normal persons, in patients with uratic arthritis the increase is on the whole less marked There is apparently a renal threshold for uric acid, corresponding to 4 or 5 mg per hundred cubic centimeters of uric acid in the serum on the average in normal persons, somewhat higher in patients with uratic arthritis Attempts at inducing acute attacks by the administration of foods containing purine or by a ketogenic diet maintained for a longer time as a rule gave negative results Signs of a slight reduction of the liver function or injury of the liver parenchyma were found in twelve of the twenty-six patients There was polycythemia in three patients and anemia in two In acute attacks of uratic arthritis the sedimentation speed of the erythrocytes was generally increased In six cases with a picture reminding one of the "atypical uratic arthritis" described in the literature, the history failed to support the diagnosis, and until the theoretical possibility of such cases without acute attacks is supported further by definite observations and until the knowledge of the etiology and pathogenesis of true rheumatism is more complete the author advises conservatism in diagnosing "atypical uratic arthritis"

Patho Anatomic Research and Nature of Tumors A Saxen —p 227.
*Renal Complications Due to Gonorrhea Lauri Kalaja —p 230

Renal Complications Due to Gonorrhea.—Kalaja says that according to Uhle only thirteen of the cases of renal complications due to gonorrhea reported up to 1934 are certain and a lesion of the infected kidney had already occurred in nearly all the cases He reports a case of pararenal abscess in connection with gonorrheal renal infection The patient, a man aged 25, had had a slight purulent discharge from the urethra, which ceased spontaneously A month later chills and fever set in, with increasing abdominal pain A large pararenal abscess was discovered on the left side By repeated puncture more than 750 cc of pus was removed Conservative treatment was followed by recovery The urine and smears of the pus from the abscess contained gram-negative diplococci, and gonococci were established in culture from the urine, there was also a definite complement binding reaction

*Ovarian Tumors with Inner Secretory Action H Bergstrand —p 415
Features of Pathology of Musical Functions H J Ustvedt —p 420

Ovarian Tumors with Inner Secretory Action—Bergstrand says that the granulosa tumors are usually unilateral and occur at all ages, though rarely in children Often three histologically different forms appear in the same tumor The tumors have cancer-like and sarcoma-like formations but are generally benign Large amounts of estrogen are secreted and demonstrable both in the serum and in the urine Before the climacteric the tumors are associated with irregularities in menstruation and uterine hemorrhages, after the climacteric hemorrhages dominate The musculature of the uterus is

hypertrophic, the mucous membrane is hyperplastic and the glands of the mucous membrane become cystically distended. In rare cases virilism or hirsutism is seen. The Brenner tumors, although they cause no inner secretory phenomena, are probably a variant of the granulosa tumors. They are benign, are as a rule unilateral, and occur after the climacteric. The theca cell tumors, also probably a variant of the granulosa tumors, are macroscopically fibroma-like, with the configuration of the ovary and yellow softer parts; microscopically they resemble the diffuse form of the granulosa tumors. Hemorrhages occur after longer or shorter peiods of amenorrhea. Sometimes there is virilism. Luteinomas are unilateral, have a characteristic yellow appearance because of the fat-filled cells, and both macroscopically and microscopically suggest a large corpus luteum. With these tumors virilism and amenorrhea are more regular symptoms. Pathogenically the four tumor types named belong to a common group. Disgerminomas, usually bilateral, occur at puberty and a large percentage cause metastases. Histologically their structure is identical with that of seminomas of the testis. In rare cases symptoms belonging to the adrenogenital syndrome are connected with them. Many of the tumors described as arrhenoblastomas are believed to be granulosa tumors. In their most differentiated form they are said to consist of tubuli; in other cases the structure is complicated with alternating sarcomatous and carcinomatous parts which merge into one another; the first type is benign, the second malignant.

Investigations on Vitamin C Balance in Asylum Patients. O. J. Broch. —p. 525.

Pulmonary Metastases.—Olsen reports 119 cases of carcinoma and twenty-nine of sarcoma in which pulmonary metastases were diagnosed from 1932 to 1936. Excluding the cases of cancer of the breast and of the genitals there was a slight preponderance in men. About 4 per cent of the patients were under 40. Most of the patients died within a year, ten lived more than a year and two lived about two years. Of the forty patients with physical abnormalities over the lungs, thirty-three had cancer of the breast, in which involvement of the pleura is more common. The author says that in seminoma testis there seems to be a special type of metastasis, in many sarcomas there is a ball-like metastasis, and nearly half of the cases of cancer of the breast have a characteristic x-ray appearance; otherwise neither the histology of the primary tumor nor its localization determines the type of metastasis seen in the x-ray examination of the lung. With regard to lymphatic permeation, there was no case of pulmonary metastasis in cancer of the breast in which the patient had been operated on radically and given postoperative radium treatment as soon as possible. The results of roentgen treatment in thirteen cases of pulmonary metastasis are reported. A conformity seems to exist between the radiosensitivity of the primary tumor and the pulmonary metastasis. The radiosensitivity was marked in a case of malignant melanoma, one of osteogenic sarcoma and especially two cases of metastasis from seminomas. The treatment was well borne and temporary benefit followed.

64: 1-122, 1938

*Periodic Fever. E. Ask-Upmark.—p. 1.
Gullstrand's Farbenmischung Apparatus. G. F. Olsson.—p. 94.

Periodic Fever.—By periodicity Ask-Upmark means the occurrence of fairly regular pyrexial cycles, usually lasting several days. Among 346 patients with tumors of the skeletal system, diseases of the blood, lymphogranulomatosis, hyperparathyroidism and renal tumors, there were thirty-eight positive and forty-six probably positive instances of periodic fever. The period of fever as a rule averaged from eight to twelve days. Periodicity was especially noticeable in Ewing's sarcoma and in the severe anemias, particularly in the more or less aplastic cases. When the anemias improved, the fever gradually disappeared. Puncture of the bone marrow and a reticulocyte count pointed to a stimulation of hemopoietic activities during the attacks of fever, and the author concludes that periodic fever in tumors of the bone and diseases of the blood is connected with involvement of the bone marrow. He says that the periodic fever present in undulant fever, rat-bite fever, relapsing fever, trench fever, kala-azar, dengue and some other conditions may also be explained by involvement of the pathologic process of the reticulo-endothelial system in general and the bone marrow in particular and that these structures may presumably be affected in other infectious disorders. The periodic fever in malignant lymphogranulomatosis (Pel-Ebstein phenomenon) can be accounted for by the theory that periodicity is inherent in the functional activity of the reticulo-endothelial system. Enlargement of the affected spleen or lymph nodes may correspond to periods of fever. The fever after splenectomy is not infrequently typically periodic and may be ascribed to compensatory adjustments taking place in other parts of the reticulo-endothelial system. The stimulation of blood regeneration connected with splenectomy may be understood from the same point of view. The fever, often periodic, which occurs in hyperparathyroidism and disappears following removal of the parathyroid adenoma, may depend on the pathologic processes in the bone marrow. In pernicious anemia the degree of fever was found to be definitely related to the severity of the anemia, and often periodic. Involvement of the reticulo-endothelial system is also suggested in cases of fever in certain intoxications. With regard to malignant tumors in general, fever as a rule occurs especially in tumors of the hemopoietic system, which, the author asserts, seems to corroborate his general conception that periodic fever is to be encountered mainly in diseases affecting the bone marrow or the reticulo-endothelial system.

*Fatal Epinephrine Intoxication. H. Gormsen.—p. 242.
Child Psychiatry: II. Infantile and Juvenile Paralytic Dementia. G. K. Stürup.—p. 245

Fatal Epinephrine Intoxication.—Gormsen reports that a man, aged 42, with a history of bronchial asthma, treated earlier with injections of epinephrine and later with inhalation of a 10 per cent epinephrine solution in spray, used 0.6 cc. of this preparation (60 mg. of epinephrine) in subcutaneous injection through a misunderstanding. Death resulted in a few minutes. Necropsy showed hyperemia of all organs. Microscopic examination disclosed capillary and venous stasis in nearly all the organs, while the arteries in many places were empty. In the lungs there were edema and extensive hemorrhages. Small interstitial hemorrhages appeared in the kidneys. The author says that of the twenty-eight cases previously reported which are ascribed to acute epinephrine intoxication, the only certain cases are the five he cites, all due to overdosage by mistake. In two of these cases a 1 per cent solution of epinephrine was injected instead of a procaine-epinephrine solution; in the others procaine hydrochloride dissolved in a 1 per cent solution of epinephrine was used instead of the commonly applied small amount of epinephrine in a 1 per cent procaine solution. The symptoms were immediate pain in the neck, anxiety, pallor, vomiting, dyspnea, increased pulse rate and collapse, which, in connection with marked rise in the blood pressure, are like the phenomena of hyperadrenalemia paroxysms in chronic chromaffin tumors. The minimum lethal dose for subcutaneous injection seems to be about 10 mg. of epinephrine. While the histologic picture in fatal epinephrine intoxication is apparently fairly characteristic, neither the macroscopic nor the microscopic changes are specific, and since epinephrine because of rapid destruction in the blood cannot be established in the organs or blood, analyses of eventual remains of the solution used must be the decisive factor in medicolegal examination of cases attributed to epinephrine overdosage.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY-JUNE 1939

Titles have been listed or Abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1929. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "OS," Organization Section; "SS," Student Section; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2700
